By means of a sieve or pepper pot fine sawdust is sprinkled as uniformly as possible over the top of the glass, and then the machine may be set in motion by an assistant. The operator should now start tapping the rod carrying the frame, etc., and then lift the short-circuiting wire by the silk thread, S T. Whenever the machine excites, the dust will be seen to gather into lines, and the action should be stopped by dropping the short circuiting rod as soon as the desired effect is obtained. The whole secret of getting good results lies in stopping it at the right moment. The tapping must, of course, be discontinued before S C R is dropped, or the dust will get shaken out of position again.

By observing the following rules good results may be obtained with a little practice. The glass plate must be level, as otherwise the vibration produced by tapping, which is necessary to diminish friction, causes the dust to shift downwards. It should not be clamped in any way, but ought to lie loosely in the wooden frame, so as not to give vibration figures superimposed on the electric ones. The sawdust should be fine, but not powdery. That obtained from mahogany with a tenon saw or a coarse rasp does very well, and it is a good plan to blacken it with ink so as to make it more visible. Many other materials, such as tea leaves and oatmeal, will also do. When glass is used for insulating from the table, white paper should be placed below it. The dust is then easily seen against the white ground, which should be well lighted. This is the best way of looking at these curves. The glass plate should be carefully discharged in a current of hot air between each experiment.

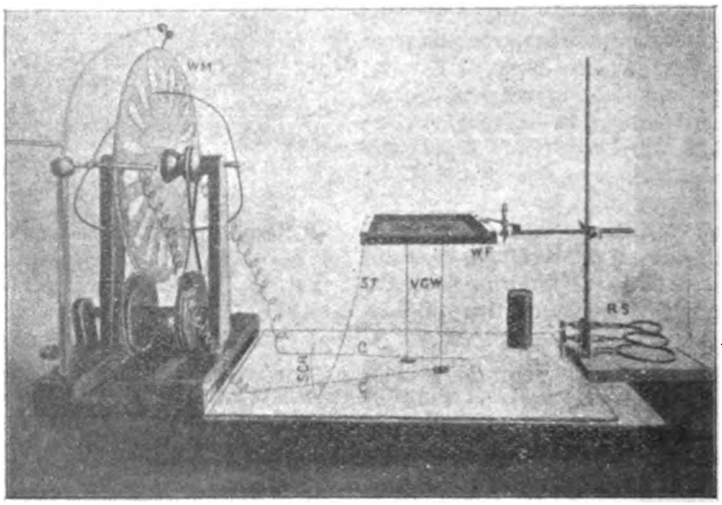

FIG. 1.—APPARATUS FOR MAKING ROBERTSON'S FIGURES ON ELECTROSTATIC FORCE.

The behavior of the dust depends very much on the material of which it is made, on its fineness, and on the state of the atmosphere. With coarse sawdust the lines often draw together, and become more strongly marked when the action is prolonged, the ends at the same time gradually receding from the foil. At other times, more especially with fine light dust, almost as soon as the lines are formed it flies off the plate, beginning at the parts immediately over the tinfoil. It is this which necessitates the rapid discharge given by the short-circuiting rod. Most of the illustrations show the effect of the commencement of this jumping off in reducing the amount of stuff in the neighborhood of the electrodes.

Several curves obtained in this way are reproduced in Figs. 2 to 7. For Fig. 2 only one electrode in the form of a circular disk was employed. We may regard this as showing the lines of force round the edges of a charged circular disk, or as the projection of those from a charged sphere. Similarly we may look upon Figs. 3 and 4 as illustrating the fields of two spheres when electrified with opposite, and similar charges respectively. In like manner Figs. 5, 6 and 7, which show the fields surrounding charged strips, may be taken to represent the fields of flat plates, of which the strips are cross-sections.

In comparing these with magnetic curves, it should be remembered that in every case the tinfoil electrodes correspond with the *ends* of

* From the "Electricial Review." London.
† See Proc. Roy. Soc., Edin., 1898-99, page 361.

Digitized by Google

magnets whose cross-sections are of the same shape as the tinfoil. Thus, the long strips do not correspond to magnets placed lengthwise, because the whole of one strip has a charge of the same sign, while the two ends of a magnet have opposite polarity.

When it is desired to fix the curves for future use, the upper side of the glass should be coated

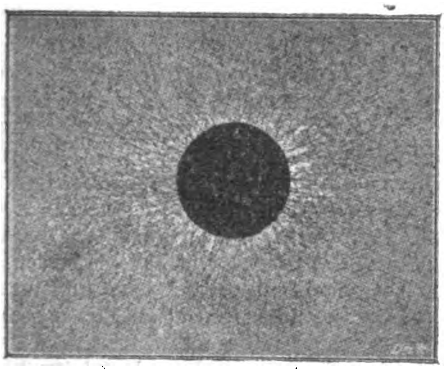

Fig. 2.—Field of a Single Disk.

beforehand with paraffin wax or a mixture of wax and vaseline. This can be done by heating the plate before a fire, and then rubbing it with a piece of the wax. When sufficient has been thus melted on to the glass, and spread as smoothly over it as possible, it is placed horizontally and allowed to cool. After the wax has

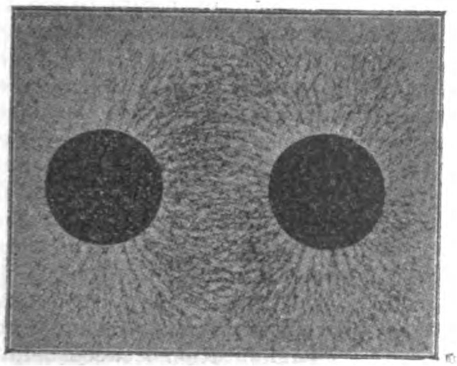

Fig. 3.—Field of Two Oppositely Charged Disks.

set, curves may be made in the same way as before, and then fixed by holding the plate before the fire again until the wax melts, keeping it level until it has again set. A cover glass should then be placed on this side, and the whole bound up like a lantern slide.

The waxed surface offers more friction than the plain glass, but in spite of this, nice curves can be obtained and fixed in this way.

The behavior of the dust may be explained

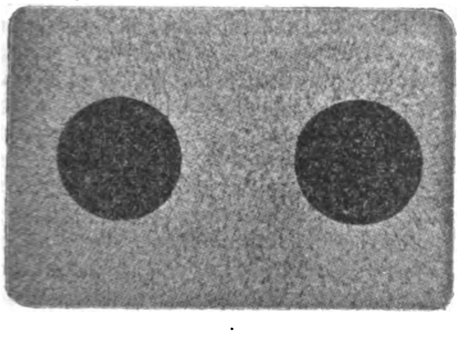

Fig. 4.—Field of Two Similarly Charged Disks.

thus. Suppose we have a number of conducting particles lying on an insulating surface, and near to these an electrode charged with positive electricity. Each particle will have a negative charge induced in its near parts, and an equal positive charge on its further ones; and since the field tends to separate these as far as possible, each particle will tend to set with its longest axis in the direction of the field at that place. We may therefore draw them in that position. It will then be seen that when two particles are exactly abreast, as A (Fig. 8), they will repel one another; but if one is a little ahead of the other, as at B, they will attract one another, and so tend to draw into line, with the result that curves are formed which show approximately the direction of the force at each point. Evidently it is preferable to have long-shaped particles, so as to let the opposite charges get farther apart, and to allow each particle itself to indicate the trend of the field. Since the attracted negative is closer to the electrode than the repelled positive, the attraction will be greater than the repulsion, and there will be a slight tendency for the particles to move towards the electrode under the conditions of the diagram. So far this explanation is on the whole the

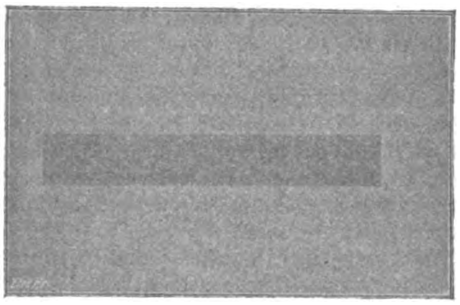

Fig. 5.—Field of a Single Strip.

same as for magnetic curves, with the substitution of + and — charges for N. and S. poles. With magnetic curves the drawing in of the filings towards the poles is very well marked.

There is, however, an important difference. The poles of a magnet cannot leave the metal, and every filing must have equal N. and S. poles, but it is possible for the electric charges

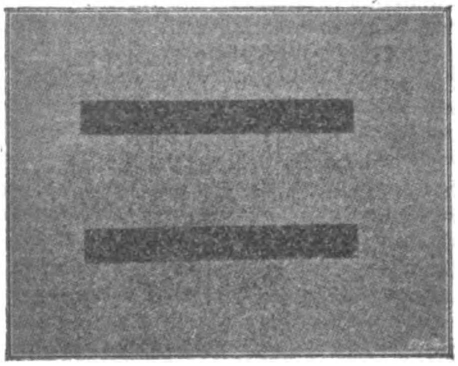

Fig. 6.—Field of Two Oppositely Charged Strips.

to leave the particles, and to have a particle with only one charge on it. Now, in our experiments, the tinfoil is slightly below the level of the dust owing to the thickness of the glass. The attracted charge on each particle will, therefore, keep towards the under side of its near end, while the repelled charge will take the upper side of its further end. Consequently, the attracted charge is more liable to be deposited on the glass. There would then only be repulsion, and no attraction, and so the particle would be driven away. This explains how the dust flies off, and why it does so most energetically above the tinfoil and its immediate neighborhood, where the force has a large vertical component. This vertical component might, of course, be eliminated, except on the top of the tinfoil itself, by placing the tinfoil side upwards, so that the dust and tinfoil come on the same side, but other difficulties then arise with the connectors, and from the fact that the dust is in actual contact with the electrodes.

There is also the possibility of charges passing from one particle to the next, and for both

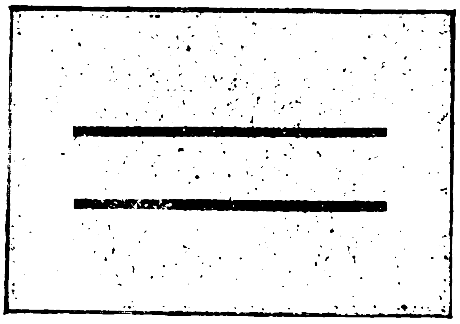

Fig. 7.—Field of Two Similarly Charged Strips.

these reasons we do not wish the material to be too good a conductor, at least, on the surface, and yet it must be a conductor to allow the induction to take place. In fact, a conducting kernel within an insulating shell would be an ideal type of particle to employ.

Again, when the electrodes are strongly charged, the electricity creeps over the surface of the glass, and so increases indefinitely the extent of surface actually acting as electrode. This is why we do not get results if they are charged beforehand.

The forces concerned are thus much smaller

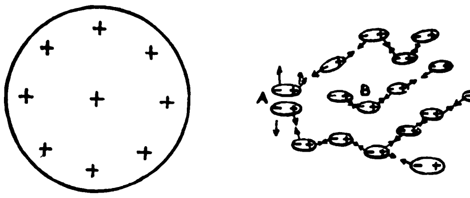

Fig. 8.—Inductive Action on the Particles.

than with magnets. Hence much more care is required, and the curves are not so strongly marked as the corresponding magnetic ones. Cases with two oppositely charged electrodes, such as Figs. 3 or 6, give the largest forces, and are therefore the easiest to obtain, while those with two like charges do not as a rule come out so sharp.

Transition of Electric Power.

A. D. Adams in "Cassier's Magazine" for October will say that with electrical distribution of water power only a small space is necessary for the few large wheels and dynamos that absorb the entire energy of the water. Mill sites, instead of being confined to a little land along the banks of a river or canal, at once expand to include the territory within five, ten or a greater number of miles of the generating plant. This expansion of surface area affects the number and character of power users. The number of industries is limited only by the water available, and the capacity of each may be either great or small. Since mill sites have come to include all the land within a long radius that is not required for other purposes, the opportunity to buy cheap power has only a slight influence on

Digitized by Google

rents. Almost the entire saving in the cost of power is thus free to be divided between the water company and its patrons.

A distinct feature of electrically distributed water power is the advantages it offers to manufacturers of small and medium capacity. The consumer of 100 horse-power will probably have to pay somewhat more per unit than the consumer of 1,000 horse-power, but the difference in rates will represent only a small fraction of that in cost which would result were a separate water wheel installed for each case.

RELATIVE ADVANTAGES OF ELECTRIC AND SHAFTING DRIVING FOR SHOP USE.*

A comparison of the relative advantage of electric and shafting driving for shop use may be made under the following general headings:

1. Relative economy in cost of power itself.
2. Relative convenience of operation and installation.
3. Relative effect upon shop output and cost of labor.

Referring in detail to the scope of these considerations:

1. Economy.—This has been taken to comprehend only the relative cost of operating the two systems, including expense for fuel, attendance, repairs, interest on investment and depreciation. It is the reason most generally advanced for the installation of electric power, but can only be the controlling one where the cost of power is a large proportion of the shop running expenses.

In order to compare the relative efficiencies of engine and electric transmission, it will be necessary to subdivide the character of shop plants somewhat. To do this completely would lead to endless complication, but for present purposes the typical plants are:

1. Shop plant in which each building has its own power plant.
2. Shop plant in which all buildings are furnished with power from a central source.

The matter of connection from the prime mover to the tools may be assumed, for an extreme comparison, in either of two ways, namely: (a) shafting method; (b) individual tool driving method.

Taking the first condition the average efficiency from engine to tools for steam engine transmission is shown to be 50 per cent.; for electric transmission, under condition "a," the shafting losses will be reduced by splitting up long lines and by avoiding cross-belting, so that they will not exceed 20 per cent., or an efficiency of 80 per cent., and in the electrical elements, as before shown, the efficiency from engine to shafting is 65 per cent.; therefore, the final transmission efficiency will be $80 \times 65 = 52$ per cent., as against 50 per cent. in the purely mechanical method; or, practically, a stand-off. Under condition "b," much less shafting will be employed, and the electrical portion may also show a better all-day efficiency, under certain conditions, by the shutting down of idle machines—say, a shafting efficiency of 90 per cent. and an electrical efficiency of 66 per cent., or a resultant of 60 per cent.—showing a gain for the electrical method.

* From a report by a committee to the Master Mechanics' Convention, held at Saratoga, N. Y., July, 1900.

Taking the second condition and assuming an unfavorable condition for shafting transmission, as in case of a shop having each building with its own boiler plant and one or more engines, and compare this with a case of a central power plant for electrical transmission to all buildings, the possible fuel saving in the latter arrangement will result first, from some small saving in power required for each individual building, as before shown, and second, from some very considerable saving due to the better efficiency of a large engine and boiler plant over that of several small ones. In extreme cases, where large condensing engines displace small non-condensing ones, and in large stations having a uniform load, the fuel saving may readily approximate 33⅓ per cent.

The item of attendance will next be considered. It is made up of three classes of labor—engineers and firemen; care of shafting and belting; electrical repairs. In an electric system the cost can be reduced by consolidating the engine and boiler plants and by the elimination of large and heavy belts, large shaft bearings and the consequent danger from overheating, reducing labor probably one-half; but a new item of expense in care of electric machinery will be introduced, which will about offset the other items, leaving the whole attendance bill practically unaffected by the introduction of electric shop power in plants of any considerable size.

As to repairs of shafting and belting, it is difficult to obtain accurate data, the record of these items being seldom kept separately in shop accounts. The records of one large establishment have, however, been examined by your committee and the saving found in these items, under the electric driving system, is found to be more than sufficient to pay for all repairs to motors and lines. Thus the conclusion seems justified that the repair item will not be materially different under either system of driving.

The remaining items of power cost are depreciation and interest on investment. It is difficult to institute a fair basis of comparison between the first cost of an electric and a steam transmission plant, for the reason that the results sought to be accomplished by the former provide additional shop facilities, and are therefore not rightly chargeable in a substitution sense. Considering, however, the case of simple substitution in a single shop, where the power plant and arrangement and number of tools is retained as before, electric driving is certain to involve a largely increased first outlay—approximately double that for shafting method. But in a modern shop plant other considerations are the guiding ones in a selection of the power system, such as the possibility of labor-saving devices, cranes, etc., and the greater cost of the electric system becomes a rightful charge against the advantages so obtained.

Dropping, therefore, any attempt to draw a strict comparison between first costs, it may be said that in estimating the total cost of power machinery it is usual to include an allowance for interest and for a sinking fund, with which to replace the plant when its utility is no longer on an equality with best practice. These items are generally figured together at 10 per cent. on first cost, a sum amounting roughly to one-fourth of the total running expenses of the power system.

CONVENIENCE AND SHOP OUTFIT.

These considerations are so closely interdependent that they can best be referred to together.

The ordinary shop plant with steam power transmission, both in the arrangement of building and of machines, is the slave to the limitations of this system; it must be laid out so that the shafting and engine connection is as direct and simple as possible; the machines must be compactly arranged in parallel lines, and the ceilings and columns designed with special reference to shafting supports. In other words, the tools must be installed with first reference to the application of power, and not, as should be the case, with reference to handling the work to best advantage. Handling operations are of necessity largely by manual methods, and the shop buildings, even, must be located with first view to getting the power to them with the least awkwardness and expense.

While generalizing in this manner, your committee has not lost sight of the fact that handling and transferring machinery may be operated by other means than electricity, but it is equally true that devices of this nature are of limited practical application, and the broad fact remains that electricity is to be credited with ushering in a new era of labor-saving shop devices.

Electrical transmission places no restriction on the location of the machines, and each shop may be planned with a view to handling its product with least waste of labor and with the greatest convenience of access to the tools. These may even be transported from place to place to the work; further, the partial or entire absence of overhead line shafting insures better lighting of the shop and conduces to cleanliness. These factors promote cheerfulness and an improvement in both quantity and quality of output.

The clear head room permits the universal application of various forms of traveling cranes for serving the tools and for conveying operations, furnishing the most efficient means yet developed for increasing shop economy, and as a means of communication between buildings, electric cranes and transfer tables have advantages over appliances of the same nature driven by steam and air.

SPECIAL APPLIANCES.

In these, electricity shares a large field with compressed air. It must be admitted that air devices have up to the present time received most attention at the hands of the railway mechanic: a fact in large part due to the lack of practical knowledge of the electrical specialist and to the greater cheapness of air tools. With, however, the general introduction of electric shop power plants and the better acquaintance of practical men with the agency, an extensive application of electric labor-saving devices is certain to result.

Flexibility.—The extension of a shop building or the tool equipment under the shafting system is generally a matter of much difficulty, and the attempt to add to such a plant often results in inconvenient crowding of the tools or to an overloading or complication of the shafting system, a fact which fully accounts for the extremely poor efficiency sometimes quoted for shafting transmission. In an electric system, on the other hand, great flexibility in extension is secured, as new buildings may be placed in any convenient position and additions made to the driving system without affecting the intermediate links.

Speed Control.—The ease of speed control between wide limits of certain types of electric

Digitized by Google

motors is a valuable feature and will result in more frequently securing a greater adaptability of the tool to the work than is possible where a change in speed involves stopping the tool and shifting belts and gearing.

Increase in Output.—This constitutes, in the opinion of your committee, the chief claim of electric transmission to the attention of shop managers, and follows from the previously mentioned facts, as, by the use of electric handling devices, the tool is quickly served with its work and the product placed in the most favorable position for operating upon and idle time cut down, and, by independent driving, the capacity is increased by reason of the perfect control of speed possible.

POWER GENERATION.*

Comparative Cost by the Steam Engine, Water Turbine and Gas Engine.

BY JOHN B. C. KERSHAW, F. I. C.

There is no question of greater importance at the present moment to those engaged in the management of our manufacturing industries than that of power generation. The supremacy which the steam engine has long enjoyed is now assailed from two sides. The water turbine and the gas engine have become dangerous rivals.

During the past ten years a most remarkable development of hydraulic power has been taking place on the Continent of Europe in France and Germany, and in America at Niagara.

The aggregate amount of power at the present date generated from falling water forms no inconsiderable portion of the total power utilized in manufacturing industries; and two years ago it was estimated by the author to be between 236,000 and 350,000 horse-power.

On the other hand gas engineers have been busily engaged in working out the problems presented by large gas engines and by the utilization of the waste gases of blast furnaces.

Gas engines up to 650 horse-power have been built, and have worked smoothly and economically; while at Seraing in Belgium and at other places the blast furnace gases have been utilized for driving the engines which supply the blast.

The question, therefore, which the engineer now has to settle when deciding upon the site and locality for a new factory, or when deciding upon the system of power generation to adopt for extensions of the old, is no longer so simple as when only one method of power generation in large units was open to him.

It is no doubt true that the choice between the three possible sources of power is one which in many cases will be settled purely by local considerations; and the proximity of a large waterfall or of an extensive coalfield to the factory will be held to point to the turbine or to the steam engine as the most economical power generator. In a great number of cases, however, especially when the decision of the engineer covers the choice of a site for the factory, the problem is capable of no such easy solution; and the most economical source of power can only be determined after an exhaustive study of comparative costs data.

The aim of the writer in the present paper has been to collect and arrange in comparable form some of the more important figures bearing on to cost of power generation. Full references are given to all the original articles from which these figures are drawn.

Tables I to VI in original article contain details of sixty-five actual or estimated costs of steam, water or gas power per hp. year of 8,760 hours.

Taking the best figures for each of the three sources of power dealt with above, and bringing them all to a common basis of comparison, namely, the cost of the ehp. year of 8,760 hours, the author obtained the figures given in the following table:

TABLE VII.—Comparative Costs of Electrical Power.

Source of power.	Lowest cost per E.H.P. year of 8.760 hours.			
	Estimated.	Locality.	Actual.	Locality.
	£ s. d.		£ s. d.	
Water.....	1 5 5	Canada.	1 19 0	Switzerland.
Steam.....	4 18 8	North England.	4 9 7	United States.
Gas (producer)....	5 0 0	England.	....	....
Gas (blast furnace)..	4 1 7	Germany.	....	....

The figures in the table support the opinion, now generally held, that water when developed without excessive capital expenditure is the cheapest source of mechanical or electrical energy. When, however, the hydraulic engineering expenditure has been heavy, or when the power after generation has required to be transmitted over long distances, the margin between the relative costs of water and steam power is greatly narrowed, and in some cases disappears.

Electrical energy generated by falling water is costing more at Rheinfelden, at Zurich, and at Buffalo than it would cost in South Lancashire if generated by steam power in large units, and the margin between the actual charge for power at Niagara and the estimated cost of steam power in large generating stations in South Lancashire is only 12s. 1d. per ehp. year.

In this connection it is interesting to note that the charge for electric power in Buffalo is 13s. 6d. per ehp. year higher than at Niagara; and the excessive charge to small consumers in the same city (£25 11s. per ehp. year) would seem to indicate that the cost of transmission between Niagara and Buffalo represents at least 20s. per ehp. year on the power sent into that city.

Turning now to a consideration of the relative position of gas power, the question of the practicability of large engines may be taken a settled. If they do not cost excessive sums for maintenance and repairs, large gas engines, in conjunction with coke ovens and blast furnaces, may entirely alter the present position of affairs; and the new industries which at present are being established in the neighborhood of water-power stations may find themselves in severe competition with similar manufactures carried on in the coal and iron districts of the older manufacturing countries.

It has been calculated that 2,000,000 hp. is annually wasted in the gases issuing from the blast furnaces of the United Kingdom. If these waste gases could be industrially utilized in the manner suggested, we should to a large extent be compensated for our lack of natural water power.

But blast furnaces demand coke, and coal beds are exhaustible, so that even if this source of mechanical and electrical energy be tapped it can only postpone, but not avert, the final triumph of the waterfall and of the turbine.

* Abstract of paper read before the British Association for the Advancement of Science, held at Bradford, Eng., Sept. 8, 1900.

THE RUBBER INDUSTRY OF THE AMAZON VALLEY.*

Of late years the enormous consumption of rubber in the manufacture of bicycle tires has created a very great demand. The supply not being able to cope with this demand, the price has steadily increased, and considerable attention is now being paid to the production of rubber all over the world. So great is the demand at present that, although the supply from the Amazon Valley alone has increased from 8,635 tons in 1880 to 25,370 tons in 1899, the approximate price of 2s. 6d. per pound in 1889 increased to 4s. 6d. per pound in 1899. The British Vice-Consul at Manäos states that the total world's supply to-day is about 120,000,000 lbs. to 130,000,000 lbs., valued at about £15,000,000. At the present time laticiferous plants yielding "caoutchouc" or "rubber" are being worked for commercial purposes in Brazil, Bolivia, Central America, East and West Africa, whence come the chief supplies, while Guiana, the Eastern Archipelago, Madagascar, India and Ceylon contribute a small quantity to the general stock. More than half the total supply is exported from the Amazon district. In Brazil several kinds of lactiferous trees exist from which rubber is manufactured. In the State of Ceara, the Manihot Glaziovii, locally known as the manicoba, is fairly extensively worked, and considerable attention is being paid to its cultivation. In the State of Maranhao the Hancornia speciosa or mangabeira is beginning to give results. These trees, however, are unimportant compared to the Heva Braziliensis or seringueira, to which the Amazon Valley owes its present prosperity. The Hevea Braziliensis is found scattered through the forests that clothe the banks of the Amazon River and its tributaries. It does not strike the eye among the innumerable varieties of trees to be met with in the Amazonian forests, and is often difficult to detect. A peculiar glistening of the trifoliate leaves and the whiteness of the bark serves as a guide to the practiced eye. The tree grows to the height of 70 feet to 100 feet, and has, as a rule, when full grown, a girth of from 5 feet to 7 feet at a height of one yard from the ground. The tree flowers in January; the seeds are ripe and begin to fall in March in the case of old trees, and in May in the case of young trees. The seeds are contained in a hard shell, three or four in each shell, which hang by a short stalk from the upper and outer branches. When ripe the shell explodes, often with a loud report, scattering the seeds to a considerable distance. For this reason it is difficult to procure seeds. There are for practical purposes three distinct varieties of the "seringueira" to be met with in the forest. These are locally known as the seringueiras "casca vermelha" (red bark), "barriguda" (bellied), and "casca preta" (black bark). The first of these, the "casca vermelha," grows in the higher parts of the forest which are seldom or never flooded. The latex which it yields is scanty, thick, and will not run. It is therefore of little value. The second of these, the "barriguda," so named because the trunk increases very rapidly in thickness towards the base, grows in those parts which are almost constantly flooded, named "igapos." It yields plentifully a thin, watery latex, which is of little value. The third varity, the "casca preta," grows in those parts where a certain amount of drainage exists, and which form an intermediary

* From the "Journal of the Society of Arts."

Digitized by Google

zone between the permanently flooded parts and the high lands. It is this variety which yields the latex from which the rubber of commerce is manufactured. The "latex," or as it is commonly known," the "milk" of the tree, is a milky juice contained in special tubes running amongst the other tissues of the plant. These tubes, in the case of the hevea, are connected, forming what is known as the "laticiferous system." The latex is quite different from what is called the "sap," and probably does not play any part in the nutrition of the tree. According to some authorities it forms a reserve of water to be drawn upon in case of drought. The actual extraction of latex cannot kill the tree, and the common statement that the trees are "bled" to death is a mistake. As a matter of fact, though, trees exhausted, inasmuch as they will not yield any more latex are common—actually dead trees, killed by overtapping, are rarely met with.

The latex as it exudes from the bark is of a dazzling whiteness, resembling milk, which it also resembles in composition, inasmuch as it consists of an emulsion in which "caoutchouc" takes the place of the butter in the ordinary milk. The fluid part of the latex consists of water with very small quantities of albuminous matter, organic acids and phosphates in solution. The extraction of the latex, or as it is usually called the "tapping" of the tree, is effected by making an incision in the bark of the tree. From this incision the latex flows for about three or four hours, after that it stops flowing of its own accord. The incision should not penetrate beyond the bark, which is generally about ⅜ inch thick, into the wood of the tree, and for this reason a very small axe, which rapidly thickens wedge like from the cutting edge is used, the shape of the instrument preventing its entering too deep. The axe is generally about ¾ inch wide. The custom is to strike with it a backhanded blow upwards, thus making an oblique cut in the bark. It is probable that a better method would be to use a chisel and mallet and make a V-shaped incision. Experiments at Henaratgoda have shown the advantage of this shaped incision. The incision having been made, a small tin cup, of a capacity of about 4 ounces, is affixed just below it to receive the latex as it flows. This is effected by pressing the edge of the cup—which is sharp—into the bark, until it gets a sufficient hold to remain firm, By this method, however, a second wound is made in the bark, which is injurious. No better method has yet been suggested. In some places a winding groove is cut in the bark of the tree, and by means of a clay breastwork the milk is conducted into a vessel placed at the foot to receive it. This method is found, however, to be very exhausting to the tree, and is falling into disuse. The usual mode of tapping is to make an incision with the axe at the height of some 6 feet from the ground; on a level with that incision and at a distance of some 8 inches a second cut is made, and so on round the tree. Next day the incisions are made just below these and so on day by day, until they reach the ground. Incisions are then made on the same plan, beginning, as before, from the top, and working downwards between the former rows.

A tree that will carry seven cups, 8 inches apart is considered a large one, and although trees that will carry eight or nine cups are to be met with, the average do not carry more than four or five. The latex having been obtained and collected, the caoutchouc, or rubber known to commerce, may be obtained from it in various ways. The only method, however, that has met with practical success is that of evaporation, by which the watery portion of the latex is driven off, and solid caoutchouc remains. The object to be secured is that as little water as possible shall remain in the caoutchouc, the putrefaction of the caoutchouc owing to the presence of these matters being extremely detrimental to its elastic properties, and therefore to its market value. In the Amazon district the method followed is to light a fire upon the ground, and to invert over it a specially-constructed, funnel-shaped chimney. From the narrow end of this funnel, which is open, the smoke and heated gases pour out in concentrated form. The fuel used for the fire consists, as a rule, of chips from any hardwood tree that grows handy to the laborer's hut. The nuts of the "Urucury palm" (Attalea excelsa) are sometimes used, their smoke containing a trace of acetic acid, and creosote being found particularly effective in curing the rubber and preventing putrefaction. It is, however, a mistake to suppose that all or even a large proportion of the rubber coming from the Amazon Valley is cured in this way. It is, on the contrary, very rarely that the rubber cutter will be at the trouble to collect these nuts, he nearly always prefers to use wood chips, which give him less trouble to procure. The fire having been made, and a large stream of hot smoke pouring out of the chimney, the operator seats himself on a small stool by the side of it. The latex is contained in a basin placed at hand. In his right hand he holds a paddle-shaped piece of wood, in his left hand a small calabash. Dipping the calabash into the basin of latex he pours a small quantity over the paddle, which he then revolves in the smoke issuing from the chimney. That having dried in a layer over the paddle he repeats the operation. In the course of time a "ball" or "biscuit" of solid rubber is thus formed. In some parts where it is the custom to manufacture very large balls or pellets, an arrangement is made by means of a pivot to rotate the ball over the chimney. The wooden core is withdrawn through a slit made in the "biscuit," or simply drawn out in the case of the pellet. The latex of a tree named "macaranduba" (Mimusops elata), and more often that of a tree named locally "amapa" is sometimes used to adulterate that of the hevea. In both cases the adulteration is extremely prejudicial to the quality of the rubber produced. Three distinct qualities of rubber are manufactured in the Amazon district, namely, "fine," "entrefine," and "sernamby" respectively. "Fine" rubber has been well smoked, and is free from putrefaction. "Entrefine" rubber has been either burnt while being smoked, or has been insufficiently smoked, and has, therefore, putrified. It is due to carelessness on the part of workmen, which it should be possible to avoid. "Sernamby" is the "negro-head" of commerce, and consists of scraps mixed with dirt, or strips peeled off the bark of the tree and mixed with impurities of all sorts.

THE people of South St. Joseph, Mo., are complaining bitterly of the inadequacy of the ambulance service in that part of the city and ask for the inauguration of an electric ambulance service over the street railway company's track as is in use in other large cities. The question will probably be brought before the city council at an early date.

THE AUTOMOBILE FOR ELECTRIC STREET TRACTION.*

BY J. G. W. ALDRIDGE, A.M.I.C.E.

The author refers to his paper read at the meeting of this section at Toronto, in which he predicted the general adoption of the overhead trolley system for tramways, and states how the system described in the paper before the present meeting will overcome the objections to that system, which are twofold, viz.: (1) The unsightly appearance of the overhead wires and supports as generally constructed. To obviate this objection, which is chiefly an æsthetic one, conduit or surface contact systems are being adopted in some towns, but it is certain that the outlay, both in first cost and maintenance, on these systems will in most cases be prohibitive. (2) The cost of electric traction in small towns and thinly populated districts, owing to the heavy expenditure on the truck and road bed. The expense of laying down an electric tramway system is, from a commercial point of view, inadmissible in many towns and districts, owing to the certainty that the traffic would not repay even a reasonable percentage upon the outlay.

Traffic facilities for the increasing population of the outskirts of large towns may be provided either by—

1. The extension of existing tramways.
2. The existing omnibus routes maintained, or
3. Motor cars adopted to replace these omnibuses.

The Extension of Tramways.—The great difficulty is the cost of the permanent way which will not be less than £4,500 per mile of single track. Assuming a five-minute service each way for 16 hours a day, maintenance at ½d. per car mile comes to £271 2s. 4d. per annum, while interest on £4,500 at 3½ per cent. is £157 10s., making a total of £428 12s. 4d. per mile, excluding all provision for repayment of capital, The cost of track maintenance varies £35 to £530 per mile; in Boston, U. S. A., and several English towns, it exceeds £500, while in Hamburg it is as low at £130. In the towns and districts under consideration this heavy charge for upkeep is likely to seriously reduce the profits on working.

The Existing Omnibus Routes Maintained.—The experience of rapid and smooth transit in the electric tramcar has sealed the fate of the omnibus of the ordinary type, and already some of the omnibus companies, recognizing this, are making substantial improvements in their vehicles. The working expenses are also heavy, no less than 8d. per omnibus mile in one large town, which may be taken as a typical example.

Automobiles to replace Omnibuses.—This is a step in the right direction, but the cars are very costly to purchase, and to maintain where a large number of passengers have to be carried. Several towns which have been experimenting with various types have abandoned them. In electrical motor cars the weight of the accumulators, often equal to that of the car and its passengers, is a great drawback; the cost of their maintenance is excessive, the commercial efficiency is low, and they have to be charged at frequent intervals during which the car is, of course, earning nothing.

The author is of opinion that the system hereinafter described offers a complete solu-

*Abstract of paper read before the British Association for the Advancement of Science, held at Bradford, Eng., Sept. 8, 1900.

Digitized by Google

tion of the difficulty; the principal features are as follows:

1. No permanent way is required.
2. Overhead equipment is reduced to a minimum.
3. The electric motor cars have no accumulators to carry.
4. The system is worked from the same generating station and feeders as the tramway system.
5. The first cost is, therefore, enormously reduced.
6. The motor cars or omnibuses may run through any street which allows vehicular traffic.

The system described is an arrangement by which a service of electric motor vehicles derives the power from a pair of trolley wires supported on short brackets along one side of the road; on these wires runs a two wheel trolley containing a small electric motor for its own propulsion, the whole being connected to the omnibus by a flexible cable attached to a pole on the roof, devices being provided for keeping the cable sufficiently taut, and to obviate any risk of derailing the trolley. Continuous current at 500 volts is supplied to the omnibus motor via the trolley wheels and flexible cable, which also contains three small conductors which serve to convey back to the trolley motor the three-phase current which drives it. This is derived from the omnibus motor, which is provided with three collecting rings on the armature at the end remote from the commutator, and connected to suitable points in the winding. By this arrangement synchronism is maintained between the speeds of the vehicle and trolley motor, but on addition, there is provided on the trolley motor an electro-magnetic brake which can be energized at will through a sixth wire in the flexible cable. The system is in actual use in the outskirts of Paris, and the paper is illustrated by numerous lantern slides showing the type of omnibus used there and details of the simple overhead construction; also by a series of cinematograph pictures showing an omnibus threading its way in heavy traffic, an omnibus turning circles and reversing its direction, two omnibuses meeting and exchanging trolley cables, etc.

The omnibuses illustrated are especially built vehicles, weighing about three tons empty and 5 tons loaded, and are furnished with solid rubber tires; at ordinary speeds the power required to propel them is from 130 to 160 watt-hours per ton-mile on level roads.

Old-Time Telegraphers' Association.

The Old-Time Telegraphers' Association and the U. S. Military Telegraph Corps met in Minneapolis, Minn., September 18. F. E. Macfarlane, president of the Bell Telephone Company of Montreal, was elected president of the Old-Time Telegraphers to succeed H. C. Hope, of St. Paul. Mr. Hope introduced Mayor Robert Smith, who welcomed the two associations. In token of the city's hospitality the mayor gave a large golden key to James D. Reid, founder of the Old-Time Telegraphers. Mr. Reid discussed the telegraph wire as an important bond between nations, and then gave President Hope a Morse medallion to be worn by successive presidents of the Old-Time Telegraphers. J. E. Hutchinson, superintendent of the Ottawa Street Railway Company, was chosen vice-president. John Brant, manager of the Western Union at New York, was re-elected secretary-treasurer.

THE NEW YORK STATE STREET RAILWAY ASSOCIATION.

The eighteenth annual convention of the New York State Street Railway Association was held on September 18 and 19, at the Iroquois Hotel in Buffalo. The Association was called to order by President Rogers, Mayor Diehl welcoming the members to Buffalo, and President Rogers responding. The President then delivered the annual address, which was in part as follows:

"Although there has been considerable extension of city roads into the country, as well as building of interurban lines during the past year, some who contemplate still further extensions are awaiting a reduction in the price of steel and other materials, and the settlement of the political question, which now confronts us, before carrying out their plans.

"Before the smaller cities and towns of our State can expect any very radical improvements in their street railroad construction, or can render the service the public demands, the law requiring the street railroads to pay for pavements must be amended. Much has been said and written upon this subject, and I believe the public is aware of the unfair and unjust burden that is being placed on the small roads in these localities. It is the duty of the State of New York to rectify this serious error, which, in nearly every instance, means in the end a receiver, as has been illustrated throughout the State. The smaller cities try to impose the same burdens on street railroads as do the larger cities upon their roads. What might not be a heavy burden to the one means destruction to the other. The suggestion has been made that each municipal body granting a franchise should be authorized by the statute to make a special contract with the applying corporation for either the construction or maintenance of pavements in the whole or different sections of the locality. The lack of elasticity in the present statute militates strongly against the best requirements of small cities for the joint interests of the roads and the public.

"Street railroads have not, in my opinion, anything to fear from the competition of the horseless carriage. This vehicle may be used for carriage and cab purposes to some extent. The 'loco' or 'auto' is still the fad, however. We hope that the many inventors now working on the various vapor motors for the 'auto' may produce something that will prove practicable and economical for street-railway operation.

"It would be an oversight if some allusion were not made at this time to the wonderful development of the street railways of the State during the last year, particularly in cities of the first class. As a matter of fact, the improvement of the street-railway service of New York, Brooklyn and Buffalo during the last twelve months has been almost startling in its character, and is an object-lesson in rapid transit for the country at large.

"The advancement and improvement of the excellent street railways of Buffalo and vicinity will undoubtedly be exhibited in a practical way by our host, the International Traction Company. I have no doubt you will all derive great pleasure from the general inspection of and the ride over the several lines which go to make up the splendid system for which the locality is justly celebrated."

Mr. Patterson, legal representative of the Metropolitan Street Railway of New York, spoke when President Rogers concluded. His subject was "Accidents on Street Railroads, Methods Employed for Handling Same and Preparation for Trial." He said there are now 1,900 cases pending against the company, calling for damages amounting to $16,000,000.

The subject was discussed after Mr. Patterson finished. Secretary Robinson, a solicitor employed by the Metropolitan Company, said that he received 60 claims for damages every day. Other men described their methods of settling claims and told on how trivial pretexts certain claims are made. One railway man said that in his city there was at least one man who made his living by receiving slight injuries and suing the railway company. The treatment of that topic brought out much humor and valuable information.

Other addresses were made. A list of them with the speakers follow:

"Railway Power Transmission," by J. H. Armstrong, Schenectady; "How Can We Increase the Efficiency of Our Employes?" by E. G. Connette, Syracuse; "Storage Battery, Its Use on Small Roads," by B. B. Nostrand, Jr., Peekskill; "Storage Battery," by Thomas Henning, Buffalo; "Description of the Rochester & Sodus Bay Railroad," by T. J. Nicoll, Rochester; "Compressed Air Motors," by H. H. Cook, New York; "Tests of Buffalo Railway Power-house," by Prof. Norris, Cornell University; "Rotary Transformers," by R. E. Danforth, Buffalo; "Practical Experience in the Operation of Combined Public Franchises by One Company," by C. E. Ueberlacker, Elmira.

On the morning of the 19th a short business session was held after which the members visited Niagara Falls.

The following officers were elected for the ensuing year: President, G. Tracy Rogers, Binghamton; first vice-president, John W. Boyle, Utica; second vice-president, E. G. Connette, Syracuse; secretary, Henry Robinson; executive committee, H. H. Vreeland, New York; L. C. Rossiter, Brooklyn; Carl W. Ely, Buffalo, and T. J. Nicholl, Rochester.

The Association will hold its next convention in Rochester.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

The Calgary Water Power Company has made a new proposition to the town of Calgary, Northwest Territories, for street lighting. The company agrees to erect new poles and adopt enclosed arc lamps.

The corporation of the city of St. Catherines, Ont., is about to undertake the development of additional water power from the Welland Canal above Thorold.

A special committee of the council of the city of Charlottetown, P. E. Island, has been appointed to obtain information in respect to the cost of a municipal electric lighting plant for the city. An estimate already received places the cost in the neighborhood of $20,000.

The electric light station of the town of Cayuga, Ont., was recently destroyed by fire, and the ratepayers of the town have appointed a committee to investigate and report as to the desirability of operating the lighting plant under municipal ownership and control. The most modern power and dynamos will be secured.

The council for the town of Almonte, Ont., has decided to submit to the ratepayers of the

Digitized by Google

town a by-law for raising a sum of money to install an electric light plant in the town. This will again bring before the ratepayers the question of municipal electric lighting, which was submitted last year and defeated after a close contest. The vote will be taken at the end of October next.

A threatened strike of street railway men, in Toronto, has been averted by a compromise. The men, who are getting 16 cents an hour, ask 20 cents. President Mackenzie offered 17 cents to those who had been two years in the company's employ, and 18 cents to those of five year's service. This offer was accepted. Mr. Mackenzie, after getting a return of wages paid in the chief American cities, was of the opinion that the Toronto men could maintain as high a standard of living as any car employes on the continent. The majority of the men have served five years with the road. The increase in the wage account will be about $40,000 per annum, but the company's earnings this year are increasing at the rate of about $150,000 a year.

SOCIETY NEWS.

American Institute of Electrical Engineers.

The 146th meeting of the Institute will be held at 12 West 31st street, New York City, this (Wednesday) evening at 8 o'clock. A paper will be presented by Prof. Henry S. Carhart, entitled "The Imperial Physico-Technical Institution in Charlottenburg." The author spent the last few months of 1899 at the Reichsanstalt as a scientific guest, and has thus been afforded an excellent opportunity for studying its practice.

Applications have been received from the following candidates for associate membership, which will be acted upon by the council at its meeting October 24: Charles T. F. Hassler, Riga, Russia; L. H. Wolf, Honolulu, H. I.; A. M. Patitz, Milwaukee, Wis.; August Parshall, London, Eng.; Percy Holbrook Thomas, Pittsburg, Pa.; Philip K. Stern, Warren Ray Thompson, Irving E. Burdick, New York City; Louis Glass, San Francisco, Cal.; Louis B. Wheildon, Boston, Mass.; Howard Scott Webb, Orono, Me.; Carl Emil Wieselgreen, Yonkoping, Sweden; Nathan Marion Snyder, Gering, Neb.; George W. Fowler, Westfield, N. J.; Samuel J. Smith, Charlotte, N. C.; John B. Whitehead, Jr., Baltimore, Md.; Arthur B. Stitzer, Philadelphia, Pa.; C. Sidney Aylmer-Small, Passaic, N. J.; Edward Heitmann, Jr., Pittsfield, Mass.; Walter N. Walmsley, Pomeroy, O.; Henry Rustin, Buffalo, N. Y.

The next meeting of the Institute will be held in New York City October 24.

The New York Electrical Society.

The members of the New York Electrical Society are invited by the American Electro-Therapeutic Association, which is holding its tenth annual meeting in New York City, to attend a lecture at the Academy of Medicine, 17 West 43d street, by Charles T. Child, on "Methods of Generating and Transforming Electric Currents for Therapeutical Uses," at 9 o'clock to-night, Wednesday, September 26.

Exports of Electrical Material from New York.

The following are the exports of electrical material and machinery, from the port of New York, for the week ended September 19:

Antwerp, 23 cases, $1,568; 8 packages, $378; 6 cases motors and parts, $257; Argentine Republic, 546 packages, $31,355; Australia, 6 cases, $886; Brazil, 10 cases, $156; British Guiana, 16 cases, $424; Brussels, 18 cases, $1,170; Cartagena, 23 cases, $4,171; Central America, 103 packages, $2,515; Christiania, 1 box motor cars, $350; Copenhagen, 1 case, $11; 7 packages motors, $1,350; Cuba, 1 case, $85; Ecuador, 1 case, $23; Genoa, 1 case, $42; Hamburg, 107 cases, $13,578; 4 packages, trolley poles, $82. Havre, 70 cases, $3,980; Hayti, 5 packages, $37; Helsingfors, 1 motor car, $275, Hull, 3 boxes motors and parts, $111; Liverpool, 2 packages, $50; 62 cases, $1,072; 6 cases motors, $1,080; London, 119 packages, $5,427; 358 cases, $13,101; 68 boxes motors, $5,918; 3 crates automobiles, $2,300; Manchester, 34 packages, $8,466; Mexico, 17 cases, $999; Naples, 1,333 packages, $72,856; Newcastle, 16 boxes, $1,595; Peru, 32 cases, $1,134, Preston, 1 case, $191; Riga, 38 packages, $3,744; Salonica, 1 case, $10; Southampton, 16 cases, $2,416; Stockholm, 1 box motor cars, $350, U. S. Colombia, 52 cases, $1,474; 37 packages, $1,500.

PERSONAL MENTION.

Prof. F. B. Crocker has returned from Europe.

Col. L. Victor Baughman has been elected president of the electric road to be built from Washington City to Gettysburg, Pa.

Mr. J. E. Nicholas, for years with the Siemens & Halske Company, is now engaged in the accounting department of the Gregory Electric Company, Chicago.

Mr. L. S. Jenkins, of the Jenkins Electrical Company, York, Pa., recently returned home from Chicago, where he has been purchasing machinery for the manufacture of telephone appliances.

Mr. E. E. Schwarzkoff will start a new weekly paper in New York called "Automobile Topics."

Mr. Rutherford Pratt Hayes is at Asheville, N. C., making arrangements to build an electric railway from that town to the sulphur springs, five miles distant.

INCORPORATIONS.

The Washington Electric Light Company, Washington, N. J. Capital stock, $50,000.

The Bluff City Electric Light & Gas Company, Council Bluffs, Ia. Capital stock, $150,000. Incorporators: T. Bowman and J. P. Greenshields.

The Westmoreland Light, Heat & Power Company, Wilmington, Del.—to produce gas and electricity for light, heat and power. Capital stock, $500,000. Incorporators: G. W. Kimball of Wilmington, E. E. Robbins, M. L. Painter, W. Lake and E. H. Bair, all of Greensburg, Pa.

The Hoosick Falls Electric Company, Hoosick Falls, N. Y.—to furnish electric light. Capital stock, $5,000. Directors: Willis E. Heaton and Ezra Tiffany, Hoosick Falls; George W. Davenport, Winchester, Mass.; Owen D. Young, Cambridge, Mass., and Clarence N. Greey, Boston, Mass.

The Archibald Brady Company, Syracuse, N. Y.—to construct street surface railroads, electric lighting plants, telephone, telegraph and gas plants. Capital stock, $50,000. Directors: William K. Archibald, New York City; Paul T. Brady and Robert E. Drake, Syracuse.

The Acme Gas Company, Chicago, Ill.—to operate gas and electric light plants. Capital stock, $50,000. Incorporators: C. W. Smith, F. R. Hughes and W. M. Cowen.

The Eagle's Mere Light Company, Eagle's Mere, Pa.—to furnish light, heat and power by electricity. Capital stock, $1,500. Incorporators: Elizabeth G. Reighard, W. Emery, J. R. T. Ryan, all of Williamsport; B. G. Welch, of Eagle's Mere, and H. Brown, of New York.

COMING ELECTRICAL EVENTS.

American Electro Therapeutic Association—Will meet in New York City Sept. 25-27, 1900.

American Street Railway Association—Will meet in Kansas City, Mo., Oct. 16-19, 1900.

National Association of Municipal Electricians—Will meet in Pittsburg, Pa., Sept. 25-27, 1900.

Roentgen Society of the United States—Will meet in New York City Dec. 13-14, 1900.

COMMERCIAL PARAGRAPH.

The American Battery Compound Company, Chicago, Ill., manufacturer of American Battery Compound, a battery salt of superior quality to replace sal-ammoniac in all zinc-carbon cells, has removed its office and factory from 31-33 South Canal street to more commodious quarters at 224-226 South Clinton street. This step was made necessary by the rapid growth of the firm's business, which was wholly beyond its expectations. The new factory has a capacity of 15,000 packages of compound per day, and the company say it is now in a position to fill all orders promptly and would like to correspond with supply houses, telephone exchanges and others now buying sal-ammoniac.

ELECTRICAL PATENT RECORD.

[This department is edited by OSCAR A. MICHEL, Solicitor and Attorney for AMERICAN AND FOREIGN PATENTS, at 302 and 304 Broadway (Room 1204), New York City, also at 639 F street, N. W., Washington, D. C., who has been identified with this work before the U. S. Patent Office for more than fifteen years. Any inquiries upon the above subject as well as printed publications containing all information regarding the cost of United States and Foreign Patents, Trade Marks, Designs, etc., will be given free upon application by addressing OSCAR A. MICHEL, Nos. 302-304 Broadway, New York City, N. Y., or 639 F street, N.W., Washington, D. C. Copies of any patent published can be furnished upon payment of ten cents. When ordering give name, date and title of invention wanted.]

LETTERS PATENT ISSUED SEPTEMBER 18, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

658,075. Electric-Railway System. William Robinson, Boston, Mass. Filed Sept. 22, 1897.

658,243. Trolley. William A. Daggett, Vineland, N. J. Filed May 23, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

657,908. Speed-Regulator for Dynamos. Philemon W. Alexander, Tifton, Ga., assignor to the Alexander Company, same place. Filed Feb. 7, 1900.

657,984. Electric Measuring Instrument. Jesse Harris, Lynn, Mass. Filed July 20, 1899.

658,012. Dynamo-Electric Machine. Mark H. Hurrell, Wimbledon, England. Filed Feb. 13, 1900.

658,022. Maximum-Electrical-Current Indicator and Recorder. Ernest C. Rimington, London, England. Filed May 3, 1900.

658,064. Switch for Alternating Electric Currents. Bertram Hopkinson, London, England. Filed Dec. 22, 1899.

658,100. Armature for Multipolar Dynamos. James J. Wood, Fort Wayne, Ind., assignor to the General Electric Company of New York. Filed June 14, 1898.

658,225. Circuit-Controller. Charles C. Webster, Asbury Park, N. J. Filed Jan. 19, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

658,301. Telephone Relay. William G. Urmson, New Brunswick, N. J., assignor of three-fourths to John W. Parsons, Henry A. Hull and Josiah Tice, same place. Filed Feb. 5, 1900.

MISCELLANEOUS.

657,910. Metallic Cement for Electric-Conductor Joints. Willard F. Barber, Wilkes-Barre, Pa. Filed Feb. 3, 1900.

657,911. Apparatus for Separating Metals from Ores by Electricity. George D. Burton, Boston, Mass. Filed Nov. 1, 1897.

657,956. Graphophone-Cylinder. Ademor N. Petit, Newark, N. J. Filed Nov. 15, 1899.

658,018. Coin-Controlled X-Ray Apparatus. Fritz Neugebauer, New York City. Filed Jan 25, 1900.

658,027. Therapeutic Device. Andrew W. Steiger, Boston, Mass. Filed Nov. 22, 1899.

658,117. Automatic Maximum-Speed Governor for Electrically-Propelled Vehicles. Horace F. Parshall, London, England. Filed June 12, 1897.

658,193. Electric Conductor. Frederick C. Sutter, Pittsburg, Pa., assignor to the Pittsburg Transformer Company of Allegheny County, Pa. Filed Dec. 30, 1899.

658,235. Secondary Battery. Victor Cheval and Joseph Lindeman, Brussels, Belgium. Filed Jan. 19, 1900.

658,237. Electrical Warp-Stop Motion for Looms. Joseph Coldwell and Christopher G. Gildard, Fall River Mass., Filed Jan. 11, 1900.

658,282. Signal. John M. Sailer, Janesville, Wis. Filed Dec. 15, 1899.

658,299. Electric Gas Lighter. Henri de Thiersant and Hans J. Norballe, London, England. Filed May 14, 1900.

658,315. Electric Furnace. Alfred H. Cowles, Cleveland, O., assignor to the Electric Smelting & Aluminum Company of Illinois. Filed Oct. 22, 1895.

DESIGN.

33,230-33,231. Electric-Cell Body. Ernest F. Yost and William H. Smith, New York City. Filed June 28, 1900. Term of patent 7 years.

Digitized by Google

THE TELEPHONE WORLD.

Police Telephones.

The police committee of the general council of Mobile, Ala., is considering the advisability of supplementing the police telegraph alarm system with the service of the telephone. Investigations made and correspondence had upon the subject by the committee show that in a number of cities in the country the telephone proves a very useful auxiliary to the maintenance of good order and the enforcement of law. In Columbus, Ohio, it is stated, the telephone has superseded entirely the police telegraph alarm system, at a material saving in cost and maintenance of apparatus and to the satisfaction of the police department. A letter from a member of the board of police commissioners of that city asserts that the police telephone system, with 120 stations, has been installed and maintained at a smaller fixed charge than Mobile pays at present for its much more contracted Gamewell service; that the more perfect communication between headquarters and the various patrol beats results in material saving in wear of horseflesh and patrol wagons, that there is instantaneous and intelligent communication between headquarters and every policeman on duty, and every incident that calls for attention at headquarters is reported without delay. It is said that the reports received have favorably impressed the committee with the advantages of the telephones.

The New York & New Jersey Telephone Company has at last, after a prolonged struggle, triumphed over its rival in Elizabeth, N. J., the Elizabeth Telephone Company, and will secure from the city council the valuable franchise allowing the company to construct conduits in all the streets of Elizabeth where its wires run and place them underground. The franchise was passed on its first and second readings by the city council, after an exciting session that lasted several hours, the debate being marked by much bitterness. The champions of the local company were President Ryan, Councilmen Horre, Benedict, Collins and Ford. They wanted to have the Elizabeth Company given the use of the conduits or be allowed to construct conduits for its wires, and also tried to have the franchise limited to twenty-five years. They were, however, beaten at all points by a vote of 8 to 5. The company gets the franchise for fifty years. The ordinance will come up for its third reading and final passage October 1, but there is no longer any doubt of its adoption, and the successful telephone company will at once go ahead making arrangements.

The People's Home Telephone Company will shortly open its first exchange in Bessemer, Ala. There are already between one hundred and two hundred subscribers to the People's in Bessemer, and no doubt this number will be increased two-fold as soon as this excellent service is started. Work has been rapidly pushed in the construction department, and all but the details are completed. The exchange will be modern in every respect. Every improvement in mechanism connected with a telephone system is incorporated in the apparatus of the exchange, and the people of Bessemer will receive a service which is not excelled in any city of any size. The Bessemer exchange will be connected with the Birmingham exchange as soon as the latter s completed, which will be about January 1. Connection with the other exchanges at the incorporated towns of Ensley, Pratt City, Woodlawn and Avondale will be made as soon as the exchanges at these points are completed. Work on the Ensley exchange is being rapidly pushed and it is expected that the people of Ensley will be using the People's 'phones in about sixty days, and may be in less time. The service of the People's will cost $18 per year for residence anp $36 per year for business houses.

The Sunset Telephone Company has ordered that all telephones in Woodland, Cal., for which contracts expire on October 1, be removed and discontinued from that date. The company's intention is to do away with all local service and maintain only long-distance communication. The reason ascribed for this radical change is excessive taxation by the county and city. At its last session the county board of equalization increased the company's assessment $10,000, and the city increased it from $6,550 to $19,500. The company claims it cannot maintain a profitable business with such an assessment. A gang of ten linemen at work making extensive improvements in the city were called away in the midst of their work after the company heard of the increase by the city board of equalization.

The Central Georgia Telephone Company of Atlanta, Ga., was recently granted a charter for a term of twenty years. The incorporators set out in their petition that they desire to establish and operate a telephone company with its chief office in Fulton County. The capital stock of the new company is placed at $15,000, with the privilege of increasing this amount to $200,000, as may be determined by a majority of the stockholders. The incorporators are T. C. Parker, O. H. Weaver, E. Y. Mallory and J. J. Cobb.

Mr. R. L. Adams of Gadsden, Ala., who has had considerable success in merchandizing at Alabama City and other towns in that vicinity, is building a system of telephone exchanges in North Alabama. Mr. Adams has built a line from Gadsden to Rome, Ga., and another from Gadsden to Anniston. In addition to the line which he has now running to Birmingham, he has one in the course of construction from Gadsden to Talladega, and it is understood he contemplates building others, making Gadsden the "central" of his system. Mr. Adams defrays the cost of construction out of his own means, and supervises all details. He is on excellent terms with the farmers along his lines, and they see that his wires and poles are kept in working order. It is natural to suppose that the big telephone lines would be against this enterprising young man. But, on the other hand, they encourage him for reasons known to themselves. The line from Gadsden to Birmingham will probably be in operation by the first of November.

The Southwestern Telegraph & Telephone Company has contributed directly to Governor Sayers $1,000 in aid of the Galveston, Tex., storm sufferers, and its president, Mr. C. J. Glidden, has personally telegraphed the Governor a contribution of $500. The loss of the telephone company in south Texas is roughly estimated by General Manager J. E. Farnsworth at $150,000 to $300,000. The exchange at Houston is very badly damaged. It is thought that the outside construction in Galveston is leveled to the ground. The long-distance lines between Galveston and Houston are absolutely wiped off the face of the earth, and all the lines out from Houston are more or less damaged to the extent of about fifty miles in each direction. It is hoped that the long-distance lines may be working into Houston immediately.

A simple and ingenious telephone set for use in crowded situations has recently been placed on the market. The bell-ringing apparatus and battery are inclosed in a case which can be screwed to the ceiling or wall, and from this the transmitter and receiver, which are mounted on a hook-shaped handle so that when the latter is at the ear the former is convenient to the mouth, are suspended from the case by a cord. Inside the case the cord is wound up on a roller like the familiar spring curtain roller. The outfit is installed so that the telephone hangs over a desk, for example, and the act of reaching up and putting down the instrument to the level of the mouth rings the bells and calls the central. When the conversation is finished and the telephone is let go the cord winds it up again, at the same time giving the disconnection signal.

The Kentucky Telephone Association will meet in Winchester, Ky., on October 9. This organization, representing the leading independent companies, has accomplished a great deal in the way of better lines and improved service, both in exchange and toll line work. The extension of new lines during the past few months has been greater than at any period of the independent movement. Many new exchanges have also been added. London and other southeastern towns are now connected with Lebanon, Lexington, Winchester and other Central Kentucky points.

The Sunset Telephone Company is about to bring suit againt the Los Angeles (Cal.) Electric Company to compel the latter to make use of a lower voltage than at present. It is claimed that the electric company's wires are so charged with electricity that it escapes and interferes with transmission on the telephone wires by causing a buzzing which renders it very difficult to carry on a conversation. In case the electric company refuses to reduce its voltage, the telephone company will demand damages.

A telephone company has lately been organized in Sioux Rapids, Ia., composed of the following local business men: Messrs. P. J. Cilley, R. H. Hulett, A. Tymeson, Jr., and W. B. Mills, to operate and maintain a local telephone line in Sioux Rapids. The line will be built and put in operation in less than sixty days. The company will be incorporated under the name of the Sioux Rapids Telephone Company.

Through failure to deposit with Kansas City, Mo., the $50,000 guarantee of good faith required by the franchise ordinance, the Missouri Interstate Telephone Company, which proposed to compete with the local Bell monopoly, forfeited the franchise voted it by the city council a short time ago. The company asked a 60-day extension of time, but the aldermen at their meeting refused this.

President Sabin of the Pacific Telegraph & Telephone Company of San Francisco, Cal., lately accepted the proposition of the mayor to reduce the cost of telephones from $7.50 to $5 a month, to bring the telephone expense within the appropriation.

According to a dispatch from Cheyenne, Wyo., the long-distance telephone line between Salt Lake and Denver will soon be completed. The connecting link between Rock Springs and Green River is now being put in and it is expected that the people of Salt Lake and Denver can hello to each other in a few days. The line passes through Cheyenne, Laramie, Gold Hill, Saratoga, and the rich mining camps of Grand Encampment and Battle Lake, Rawlins, Rock Springs, Green River and Evanston to Ogden and Salt Lake.

The Mississippi Valley Telephone Company is doing a large amount of work in St. Paul, Minn., and is only waiting for the necessary wire to connect 3,000 additional subscribers. Charles F. Weismann, St. Paul manager and secretary of the company, says the wire was ordered six weeks ago and paid for in advance. It is expected that the shipment of it will begin shortly, and as soon as the material arrives crews of men will be put at work to complete the extension of the exchange. Mr. Weismann says that 3,000 new 'phones will be connected inside of sixty days.

News from Vermont states that Barre's Independent Telephone Company is bound to be a go, as sufficient stock has been subscribed for to insure the construction of a first-class line, and it will have 221 telephone subscribers to start with. The committee having the matter in charge recommended that a start should not be made until 200 shares of stock had been subscribed for. This has been accomplished, as exactly 201 shares have been taken.

H. W Pope, general manager of the Bell Telephone Company of Buffalo, N. Y., announced recently that as soon as the switchboard is set up and in use in the main exchange it is expected that the telephone service will be greatly improved and that inconveniences that patrons have suffered during the course of recent improvements to the system will be eliminated.

The Missouri & Kansas Telephone Company has commenced an extension of its line from Oswego to Independence, Kan., and west to Winfield. This will give Independence and the other towns along the new line direct telephone connection with Kansas City and the towns in eastern and western Missouri. Several car loads of telephone poles have arrived in Independence, and a gang of workmen are to set them in position.

Messrs. R. M. Chowning, of Fulton, Ky., and J. E. Wright, of Mayfield, Ky., the majority stockholders and managers of the West Kentucky Telephone Company of that section, have been offered the management of a large telephone company at Evansville, Ind., involving a deal of $150,000. Mr. Wright has lately been to Evansville examining into the deal.

A telephone line is being constructed from the Charleston & Western Carolina depot at Crocketville, S. C., a distance of about four miles. Messrs. Fred Lightsey, of Crocketville, and Eugene M. Peeples, of Hampton, are the proprietors of the new enterprise.

The stockholders' meeting of the Mutual Telephone Company of Des Moines, Ia., which was called about a month ago, and postponed, will be held to-day, September 26. The directors are anxious that a full meeting shall be held at that time. The proposed changes in telephone rates to stockholders will come up for settlement at that meeting.

The mayor and aldermen of Biddeford, Me., granted to the Biddeford and Saco Telephone & Telegraph Company a permit to locate its poles and wires on a number of streets, ignoring the petition of the New England Telephone Company for rights covering the same territory.

The Hudson River Telephone Company of Newburgh, N.Y., is making arrangements for putting up a cable along some of the streets of that city. There will be about 120 wires in the cable, which will replace the 40 or 50 wires which have disfigured the streets for some years.

The telephone company established in Marietta, O., by J. W. Dusenbury and other Columbus people, opened for business a short time ago. The Bell Company has begun to cut rates.

On account of the large increase in business at the Cotton Exchange of this city it has been found necessary to augment the present telephone service by the installation of eight new instruments.

The new telephone system for High Springs, Fla., is being rapidly placed in position, the poles for same having been put in the ground.

Poles for the long-distance telephone lines have been distributed between Easton and Yakima, Wash.

GENERAL NEWS.

What is Going On in the Electrical World.

LIGHTING.

Abbeville, La.—M. T. Lewman & Co., of Mobile, Ala., has made a proposition to the city for the erection of a $42,000 water and electric light plant.

Adrian, Mich.—The Gilliland Electric Company of this city, is advised of the destruction of its branch plant by fire, at Belington, W. Va.

Alliance, O.—Bids are being received for the erection of an electric light plant at this place.

Altoona, Pa.—The Altamonte Hotel is preparing to put in an electric light plant of its own.

Ava, Ill.—The Ava electric light plant was totally destroyed by fire. Loss $3,000.

Billings, Mont.—Bids are asked until October 2 for furnishing 50 electric lights for a period of six years. Address J. B. Herford, clerk.

Canton, Ga.—The Georgia Marble Finishing Works of this place wants to buy a dynamo for 50 incandescent lights.

Cape May, N. J.—Lemuel E. Miller has selected a site in the western portion of Cape May on which he will erect an electric light plant to supply public lighting.

Carbondale, Pa.—The electric light power house is to be greatly improved in the near future. The old machinery is to be replaced by more modern apparatus.

Chicago, Ill.—At a recent meeting the village board of Harlem voted to advertise for bids for the construction of an electric light plant to furnish 2,500 incandescent lights to private parties. The proposition was made by Trustee F. Meyer.

Clinton, Ill.—The Clinton Electric Light Company will install new arc light machinery.

Cumberland, Md.—The city officials are considering plans for enlarging the municipal electric lighting plant.

Dallas, Tex.—The Dallas Electric Light Company will install a new plant of 1,200 incandescent lights.

Dyersburg, Tenn.—Plans are on file for an electric lighting plant to be installed in this town. Address W. A. Faulkes, mayor.

Henderson, N. C.—The Seaboard Knitting Mills recently contracted for the installation of an electric light plant.

Houston, Tex.—Bids are asked until November 5 for constructing a complete electric light plant in this city. Address A. Lipper, city secretary.

Kennett, Mo.—The council is considering the question of having some additional lights put in throughout the city. If the plans are carried out the local plant will need additional machinery. C. Sickles, manager.

La Crosse, Wis.—Alderman Schultze offered a resolution, which was adopted, instructing the mayor to appoint a committee of five to investigate the matter of establishing a municipal lighting plant.

Little Falls, N. Y.—As predicted some time ago it now seems certain that the Herkimer County Light & Power Company will secure the Dolgeville electric plant.

Longueuil, Que.—At a recent meeting of the council a report submitted by the light committee, recommending that tenders to light the streets by electricity be called for, was adopted.

Los Gatos, Cal.—The town board is considering the proposition of several improvements, among which is the owning of an electric light plant.

McKeesport, Pa.—The finance committee of the city councils added on to the proposed bond issue a short time ago another $50,000 to be used in erecting a municipal electric light plant.

Monticello, Ill.—The Monticello Electric Light Company has decided to put in a heating plant for warming stores and residences.

Muscatine, Ia.—The Muscatine Electric Light & Power Company is now preparing to proceed to build a new plant to meet the needs of the present business.

New Haven, Conn.—The United Gas Improvement Company will make a strong effort to establish a new electric light plant in Bridgeport and this city this winter.

New London, Conn.—Bids are asked until September 29 for delivering at this city 250 incandescent lamps. Address Major S. A. Leach, U. S. engineer.

New Portland, Me.—C. H. Bartlett, proprietor of the novelty mill here, will soon add an electric light plant to his establishment.

North Toronto, Ont.—The property owners of this place recently held a meeting for the purpose of forming a town improvement association, which shall take steps to secure better roads and sidewalks, electric lighting, the beautifying of the residences and grounds and the general improvement of the town.

Rockville, Ind.—A recent fire destroyed the city electric light plant, but fortunately the city has an entirely new light plant under course of construction, the machinery being almost completely installed, so that by crowding the work the city will soon be lit by electricity again.

Sioux Rapids, Ia.—A deal has been completed whereby O. M. Packard disposed of his interests in the electric light plant at this place to L. L. Mertz, of Keithsburg, Ill. The new owner will give the plant his personal supervision.

Thessalon, Ont.—The city council will soon take up the question of installing an electric light plant.

Thomasville, Ga.—The Thomasville Electric Light Company has been placed in the hands of a receiver.

STREET RAILWAYS.

Belfast, Me.—H. L. Kochersperger is interested in the proposed electric road to be built from here to Northport.

Bristol, Va.—The Bristol Belt Line Railway Company has obtained a franchise to use a number of the town streets for its electric system.

Brooklyn, N. Y.—A resolution to compel the Brooklyn Rapid Transit Company to put its trolley wires under ground was introduced by Alderman Alt at a meeting of the board last week. It was referred to the committee on railroads.

Cleveland, O.—The Cleveland City Railway Company will begin the work of changing the Payne Avenue cable line to electricity about October 1. G. G. Mulhern, general superintendent.

Frankford, Del.—The citizens have offered to contribute $5,000 toward the construction of the proposed trolley road from this place to Ocean View.

Grass Lake, Mich.—The common council at a recent meeting granted a franchise to W. A. Boland to operate an electric road through this village for a term of 30 years.

Grimsby, Ont.—The Cataract Power Company contemplates building an electric railway from Hamilton to this place, as a rival to the Hamilton, Grimsby & Beamsville line, and later on may extend to Niagara Falls.

Lewiston, Me.—It is said that the prospect of building the electric road to this place by way of Winthrop is brighter than ever.

Lowell, Mass.—A petition for a new electric railroad has been filed with the selectmen of Billerica and other towns. Starting at the termination of the Boston Elevated in Belmont, the proposed line is through Woburn, Burlington, Lexington, Lincoln, Concord, Billerica and Chelmsford to this city.

Nyack, N. Y.—C. W. Reeve is interested in a proposed trolley system for this place.

Ripley, O.—A promoting company was organized here a short time ago to construct an electric railway northward on a capital of $10,000.

Rochester, N. Y.—A trolley line that will connect this city with Buffalo by way of the famous Ridge Road in the northern section of Niagara County is believed to be assured. Rights of way have been secured. Branch lines will be run to Medina and Albion. It is promised this road will be in operation early next summer.

Sherman, Tex.—J. P. Harrison and others are considering the formation of a company to build an electric line in the eastern part of this city.

Sidney, N. Y.—The Susquehanna Valley Electric Company will build a trolley line between here and Franklin. H. B. Oakham, C. F. Lehman and Ed. H. Tucker of New York are interested.

Stafford, Conn.—It is possible that this place may be enlivened by an electric line if the enterprise being shown will result in such an improvement. Maro S. Chapman is one of the parties interested.

Steubenville, O.—Many new electric railway lines and extensions are projected for eastern Ohio and Pennsylvania.

Trenton, N. J.—The Philadelphia & New Jersey Street Railway Company has started a force of men at work on the construction of one of the most important trolley links in the line to Philadelphia.

Uniontown, Pa.—The Uniontown & Monongahela Valley Electric Railroad is the name of a new line soon to be constructed, and will run from here to Masontown passing through New Salem and McClelland.

Whitehall, N. Y.—By the trolley connection of Whitehall to Granville freight will go direct to Troy or even to New York City by the Champlain Canal and Hudson River. Branches are to be established in Vermont.

White Lake, N. Y.—The project of a trolley road from here to Shohola, on the Erie, is again being agitated.

MANUFACTURING.

Chicago, Ill.—J. Holt Gates & Co. of this city has been awarded the contract for the new addition to the electric light plant at Naperville, Ill. There will be installed one 120 kw. Warren alternator and a marble switchboard. There will also be installed a 300 hp. cross-compound Corliss engine; the entire plant will be run from this engine by belts running to a countershaft. This additional apparatus also contemplates a complete overhauling of the entire outfit into a modern, up-to-date plant. The same firm has been awarded the contract for the new addition to the electric light plant at White Water, Wis., which includes a 90 kw. Warren alternator.

Los Angeles, Cal.—The Palmer-Nicholls Company of Providence, R. I., is to establish a branch factory here for the manufacture of all kinds of electric wires.

Madison, Wis.—The Northern Electric Manufacturing Company of this city, Western agent for the Stanley Electric Company of Pittsfield, Mass., was recently given the contract for the new machinery for the municipal lighting plant.

New York City.—Edward Rafter, of this city, Gennaro Romanelli and Dennis M. Shea of Madison, N. J., are interested in the Romanelli-Rafter Electric Chemical Company, which was lately formed here to manufacture electrical batteries.

Pittsburg, Pa.—The L. G. Martin Company of this city will manufacture gas engines and electrical machinery on a capital of $5,000.

Wilmington, N. C.—J. Hicks Bunting of this city wants to communicate with manufacturers of combination gas and electric fixtures.

COMPANY MATTERS.

Far Rockaway, N. Y.—A special meeting of the stockholders of the Queens Borough Electric Light & Power Company will be held on October 4 for the purpose of voting on a proposition to increase the capital stock of the company from $250,000 to $410,000.

Worcester, Mass.—President Washburn of the Washburn Wire Company announces that his company has acquired a controlling interest in the American Electrical Works at Phillipsdale.

POWER AND TRANSMISSION PLANTS.

Belvidere, N. J.—It is proposed to erect an electric power plant here to use the water power of the Delaware River at Big Foul Rift, a few miles below this place. Options have been secured on a number of farms adjoining the river. The plan is to furnish electric power for the lighting of Phillipsburg, Washington, Hackettstown, Belvidere, and other near-by places.

Shingletown, Cal.—A company of Eastern capitalists has purchased 600 acres of land on Mill Creek near here for the location of a new power plant. The company will begin business with a 2,000 horse power generator and increase the capacity as required.

MINES.

Montreal, Can.—Water Superintendent Marien has prepared a report upon the probable cost of installing an electric pumping plant at the high level reservoir. He estimates the total cost at $30,000. This would provide two electric motor pumps with a capacity of 5,000,000 gallons a day. The report will be carefully studied. The work may be done in sections, by putting in one pump at a cost of $18,000.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¼@16⅜c.; Lake, 16⅜@16½c.; casting, 16⅛@16¼c.

The output of copper for 1900 expected to reach 325,000,000 pounds, worth $42,250,000, the largest on record.

All but 2,500 shares of Pratt & Whitney Co. stock have assented to the consolidation with the Niles Bement-Pond Company.

The Chicago Telephone Company declared a quarterly dividend of 3 per cent., payable October 1. Books reopen October 10.

A dispatch from Chattanooga, Tenn., states that the Signal Mountain Railway has been bought by the Chattanooga Rapid Transit Company.

The Massachusetts State Railroad Commission has authorized the Pittsfield Street Railway Company to issue $50,000 additional stock for extensions and equipment.

Stockholders of the Electro-Pneumatic Transit Company have received a circular from a law firm, inviting them to give options at $5 a share for ninety days.

The Otis Elevator Company has declared a quarterly dividend of $1.50 per share on its preferred stock, payable October 13. Books closed September 22 and reopen October 15.

The State Board of Railroad Commissioners will give a public hearing in this city Saturday on the application of the Brooklyn Rapid Transit Company to discontinue several elevated stations.

Advices from Pittsburg state that a Detroit contractor is negotiating for $610,000 worth of electrical equipment for a proposed traction road from Cincinnati to parallel the Miami & Erie Canal for 244 miles.

The Amalgamated Copper Mining Company has declared the regular quarterly dividend of 1½ per cent. and an extra dividend of ½ per cent., payable October 29. Books close September 28 and reopen October 31.

The latest quotations for some of the new industrial stocks, not given elsewhere, are: Electric Boat, 13@15; New York Electric Vehicle Transportation, 6½@7; New England Transportation, 3½@3¾; Gramophone, 35@40.

Directors of the American Telephone and Telegraph Company have declared a regular quarterly dividend of 1½ per cent. The dividend is payable October 15 to stock of record September 29. Books close October 1 to 15 inclusive.

The first fall meeting of the New York Rapid Transit Commissioners was held on the 20th inst. Contracts are let for nearly all the sections of the tunnel, and its Brooklyn extension will be acted upon at the next meeting.

The Manhattan Company is said to have completed arrangements with the Metropolitan Company by which the latter will furnish all the power and equipment needed to test the third rail system on the Manhattan road in New York. When this is successfully done work on the Manhattan plans will be proceeded with more rapidly.

An officer of the Chicago Union Traction Company denies the report that the next dividend on the preferred stock will be passed or reduced. A meeting of the board of directors has been called for September 28, in Chicago, to act on the dividend and also to elect officers for the present year. Failure to get a quorum has prevented the election of officers before.

Stockholders of the Union Traction Company of Philadelphia held their annual meeting on the 20th inst., and re elected the following directors: P. A. B. Widener, William L. Elkins, Thomas Dolan, George W. Elkins, John B. Parsons, Jeremiah J. Sullivan, William H. Shelmerdine, George D. Widener, Alfred Smith, Alexander M. Fox, Charles O. Kruger, and Alexander Balfour. Aside from reading of the annual report, the only interesting feature of the meeting was the presentation of a resolution to issue monthly earning statements.

Alderman Lamb, chairman of the City Board of Works of Toronto, Ont., reports that he has received satisfactory assurance from New York that a company to build a radial electric railway system, tributary to Toronto, would be financed in the city of New York. He urges, however, that Canadian capitalists take control of the enterprise and raise the $5,000,000 required to carry out the work. The scheme involves the construction of almost 500 miles of trolley lines, the chief one giving Toronto connection with Georgian Bay and Lake Simcoe.

More than 45,000 shares of Brooklyn Rapid Transit stock were traded in on the New York Stock Exchange on Monday and it is said that much of the selling represented long stock. In the morning, when the price slumped more than a point, a rally followed on the publication of the statement that the next quarterly earnings report would show some "surprises," the inference being that these surprises would be favorable—as, in fact, a director of the company declared would be the case. In the afternoon, however, the street heard that the promises of a favorable showing might prove to be like recent other promises in respect to the stock—disappointing. At the same time a selling movement set in, which speedily carried the price to the low figure of the day. Around 48 the stock apparently had good support.

The detail figures of the Metropolitan Street Railway Company's balance sheet for the year ending June 30 are as follows: Assets: Cost of road and equipment, $35,632,168; stocks and bonds, $21,644,457; new construction on lines owned and leased to be distributed, $18,168,360; supplies on hand, $1,03,788; improvements and betterments charged to leased lines, $2,776,164; cash on hand, $12,489,276; bills receivable, $271,886; office furniture, $18,3 4; open accounts, $37,294; total, $91,091,587. Liabilities: Capital stock, common, $44,960,900; funded debt, $21,750,000; bills payable, $8,756,736; interest on funded debt account, $401,274; dividends unpaid, $786,815; due on open account, $374,230; rentals and taxes accrued, $621,830; Third Avenue Railroad lessor construction account, $11,419,833; profit and loss surplus, $2,019,919; accounts payable, total, $91,091,587.

EDITORIAL NOTES.

The Overhead Trolley System of Brooklyn.

The Brooklyn Rapid Transit Company would seem to be having a more or less hard row to hoe. About a year ago a clique of speculators, by circulating rumors and false statements, came very nearly bankrupting the concern, while only recently the following resolution was passed by the Board of Aldermen of Greater New York:

"Resolved, That the Corporation Counsel be and he is hereby respectfully requested to begin such proceedings as are warranted under law, which will require that all surface street railroads in Greater New York, now operated by the overhead trolley system shall be operated by a system of underground currents."

This resolution, if it can be enforced, will mean that the many miles of overhead trolley system in Brooklyn will have to be replaced by the underground conduit system such as is made use of by the Metropolitan Street Railway Company of the Borough of Manhattan. The N. Y. "Commercial" referring to the subject says:

"The resolution, if adopted, could not be enforced. The power to change motive power on railroads is vested in the State Railroad Commission, and then only if the railroads apply for permission to do so. The commissioners cannot compel a railroad to substitute the underground for the mid-air system. The Legislature can, and the Legislature on behalf of the people is to be appealed to do away with trolleys above ground. The Corporation Counsel is to be asked to present the matter in the light in which the local government sees it; that trolleys are dangerous to life, and that telephone and telegraph wires strung along poles interfere with the work of firemen at fires."

There is no doubt but what the intricate network of overhead wires in Brooklyn is unsightly, and more or less of a menace to the public, to say nothing of the damage constantly being caused through electrolysis by the overhead trolley. Yet in spite of these facts drastic measures should not be hurriedly enforced, as it would mean the loss of thousands of dollars to stockholders, who have purchased in good faith the securities of the Brooklyn Rapid Transit Company.

Could this measure be enforced how seriously it would affect the finances of the company may be inferred when it is stated that the cost of changing the system would probably amount to not less than eight or ten million dollars.

It is stated that the resolution introduced at the session of the Board of Aldermen, had no political significance, and that it was purely in the interest of the public. Such may be the case, but the attack was significant to say the least, and in view of the general street railway conditions in Greater New York, it would not surprise us to see before a great lapse of time the Brooklyn Rapid Transit Company pass under the control of another well-known street railway corporation.

* * *

The Plans of the National Telephone & Telegraph Company.

When the National Telephone & Telegraph Company was incorporated with its $55,000,000 capital a few months ago in Trenton, N. J., it gave rise to a rumor that its ultimate object was to absorb all the telegraph and telephone companies doing business in the United States. This report gradually died a natural death, but has again recently been resurrected by the following brief statement, which appeared in the columns of one of our contemporaries a short time ago:

"There have been numerous rumors of late concerning the probable amalgamation of all the telephone and telegraph companies of the United States. These are the American Telephone & Telegraph Company (which now includes the American Bell Telephone Company), the Telephone, Telegraph & Cable Company of America, the Western Union Telegraph Company, and the Postal Telegraph Cable Company.

"It is predicted by those in position to know that these interests will be consolidated into one big company, to be known as the National Telephone & Telegraph Company, and that such consolidation will be accomplished before the end of the present century—which means before the end of the present year."

With a view to ascertaining whether there was any truth in this report a representative of ELECTRICITY called on Mr. William J. Latta, the well-known telephone financier and president of the Telephone, Telegraph & Cable Company of America. Mr. Latta, in reply to the questions put to him on the subject, stated most emphatically that he knew nothing about

Digitized by Google

the rumored consolidation, that he had not authorized the use of his name in connection with the matter, and that it was generally thought that the rumor was being circulated for stockjobbing purposes.

Mr. William H. Baker, vice-president and general manager of the Postal Telegraph Company, referring to this same subject, said:

"You can deny, emphatically, that the Postal is contemplating any combination with the Western Union or with the Bell Telephone Company, or that control of the Postal or the Commercial Cable Company is for sale. Mr. Mackey has stated positively that these companies are not for sale, and that they will not be consolidated with any existing companies.

"This story is one which has gained currency at various times of late. Numerous reports have been printed regarding a consolidation of telephone and telegraph companies in the United States, but so far as I know they are all entirely without foundation. The present story is merely an elaboration of a story which was in circulation some time ago, and, like the original one, is without foundation."

The charter of the National Telephone & Telegraph Company is a sweeping one, and by its provisions permits it to "construct, maintain and operate electric telephone and cable lines within New Jersey and across the Hudson with lines in New York, now or to be established, connecting with lines at Trenton, connecting with lines in Pennsylvania, in New York and in other States, Territories and colonies and foreign countries." That this corporation which has back of it many well-known and wealthy men, means to form a consolidation of some nature is not to be doubted, but what companies it proposes to amalgamate it is impossible to say at the present time, and in view of this fact little credence should be given to vague rumors.

Physicians Discuss the Effects of Electric Light on Tuberculosis.

The meeting of the American Electro-Therapeutic Association, recently held at the Academy of Medicine in this city, was the means of bringing out considerable valuable information regarding the application of electricity and electric light for the cure of tuberculosis. The physicians present were all anxious to get at the facts of the matter in view of the amount of literature that had appeared of late descriptive of alleged electrical tuberculosis cures.

The effect of electric light on consumptive patients was gone into, and the statements made would seem to bear out Dr. J. Mount Bleyer's remarks on the subject made before the Medico-Legal Society and Congress of Tuberculosis in February last. On that occasion Dr. Bleyer among other things said:

"Arguing from all that I have said, and all that is known about the blue and violet rays in conjunction with the atmospheric conditions in general, I set out to make practical application of these colored rays of light as an adjunct to the treatment of tuberculosis, in their various stages of progress, as a prophylactic in supposed early stages, etc. Much to my satisfaction, the practical experiments which I have tested in so many different conditions in tuberculosis, these tests have all given good account of themselves in most instances, so that I am very happy to make you acquainted with my results, as I have found them. I am of the positive belief, from my acquired practical and theoretical knowledge of facts, that the best method to treat tuberculosis and other forms of lung diseases, is in specially designed solariums at home or at a sanitarium where violet lights can be generated according to the requirement of each individual case, and specially treated upon principles according to the condition of each case.

"From all the reports and researches of the present day by the expert men in this branch of study, we find but one cry, and but one concert of opinion for the successful treatment of tuberculosis—hygiene, food, sunlight!"

The above opinion apparently coincides with that of Dr. Wolff Freudenthal, who, at the recent Electro-Therapeutic Association Convention, said that experiments have shown that the effect of electric light on the human body is the same as sunlight, which has been valued for centuries for curative powers. Under the influence of electric light, he said, the body gives off in breathing more carbonic acid gas, and is stimulated to greater activity. The electric treatment, he asserted, is not only painless, but pleasant, and all of his patients have insisted upon its use.

Dr. Freudenthal declared that he expects to see the apparatus for the application of electric light in cases of tuberculosis perfected very soon, and that a great step will thus be taken toward the absolute cure of that disease.

Several other physicians in discussing the value of electric light in the treatment of tuberculosis agreed that its use had been followed by remarkable results.

It is to be hoped, judging from the optimistic views taken by the physicians at the meeting in question, that an electric, or light cure, will soon be found for this dread disease.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Lieut.-Gen. Miles, in his annual report, will renew his recommendation for the use of the automobile in the army. There are now at Fort Myer, Va., three automobiles, but they have not been proved satisfactory for lack of facilities for recharging them with electricity.

Mr. Ralph B. Marchand, for some years expert for the Westinghouse Company in connection with the long distance transmission of electricity, has been appointed to a similar position with the Montreal Street Railway and the Chambly Manufacturing Company of Montreal.

An order from South Africa for electrical material has lately arrived and has been booked by an engineering firm in this city. The shipment, which is to be made to Cape Town, will aggregate some $20,000 worth.

It is proposed to erect an electric light plant at Simla, the summer capital of India. It is in the foothills of the Himalayas, and water-power is abundant. Kerosene is used at the present time.

What is said to be the largest electric crane ever built in the world has been finished by Pawling & Harnischfeger of Milwaukee, Wis., for the Midvale Steel Company of Philadelphia for use in the manufacture of armor plate for battleships. The giant crane can lift 200 tons, weighs 400,000 pounds and the cost of the piece of machinery will be $40,000. The electric crane required sixteen flat cars to transport it. The crane has a sixty-five foot span and it will be operated on a track fifty-six feet from the floor.

John D. Long, of Chicago, has invented a modern car fender. This fender is constantly under the control of the motorman and the object is to provide a receptical which is sufficiently raised to escape damage by striking any obstruction on the track. It is so connected with the brake mechanism that when the brakes are set the fender is thrown in position to scoop up any person on the tracks and further to provide a brake mechanism which will enable the brake and fender to be operated with great rapidity.

Consul Worman at Munich writes to the State Department saying that most factories in Germany have nothing like our electric timekeepers, and an effort to introduce them into Germany, especially into South Germany, where new enterprises are constantly being launched, ought to be successful.

The Harms Milling Company of Harms, Tenn., has now, in connection with its flour and saw-mill, an electric light plant, by which it runs both. The company contemplates furnishing lights not only for the mills, but to families in the locality, and if possible continuing the wire to Fayetteville, Tenn.

The Triumph Electric Company of Cincinnati, O., furnished the dynamos that drop the exhibit of the J. A. Fay & Egan Company at the Paris Exposition. They were not entered as any part of the exhibit though they naturally attracted some attention. A letter was recently received by the concern from the Paris Exposition officials, announcing that the dynamos of the Triumph Company had been awarded a medal.

A short time ago an infuriated bull was the cause of frightening thirty passengers on a Philadelphia and West Chester, Pa., trolley car. He had broken from a field and wandered along the trolley tracks. When the car came along he took up his stand between the rails, and refused to budge. Apparently the animal was incensed by the glare of the big electric headlight, and against this he bent all his energies. Backing away from the car, he charged with such fury that the car shook from end to end. This was repeated several times, and when the animal realized that he had met his match and wandered away, there were two big holes in the forward end of the car and the headlight was useless.

A story is current that hitherto the Sultan of Turkey has forbidden the importation of electrical appliances or their use by local manufacturers, on the ground that they were inventions of the evil spirit. About a month ago an American firm sent to Constantinople a consignment of electrical goods for introduction. The goods on arriving were confiscated by the Turkish customs officials. The American electrician who was sent with the goods appealed to the American Consul General, C. M. Dickinson, and after many efforts an audience was obtained with the Grand Vizier, and this official finally permitted the electrician to show how the electrical devices worked. A room in the Sultan's palace was turned over for the exhibition. The marvels of the "Wonder Room" soon spread all over the palace and the Sultan learned of them. Abdul's curiosity induced

Digitized by Google

him to inspect the mysterious contrivances, and in a moment of enthusiasm he bought the entire lot of goods in the palace and gave orders that hereafter the introduction of similar articles into the Empire should be encouraged and fostered.

A German professor by the name of Rosen berg has invented a system of wireless telegraphy which he claims is an improvement over that brought out by Marconi. The professor's idea is to reduce the size of his transmitter and receiver so that it may be carried in one's pocket. This would enable a person, so it is claimed, to walk along the street or sit in his office and communicate with his home.

Although the development of the telephone in Russia may be somewhat slow as compared with other countries, still the growth of its telephone system is very considerable. According to some comparatively recent statistics, there were in Russia an aggregate of some 35,000 miles of telephone wires—about half State and half private concerns. The use of the telephone and the number of subscribers are, however, rapidly increasing, and some important lines between some of the larger cities are under contemplation or already completed. In the Baltic provinces there are some large telephone systems, but they do not appear to be altogether satisfactorily constructed, inasmuch as the different lines, which are frequently of considerable length, have no connection with each other. This is, says "Engineering," London, mainly attributable to Government restrictions where State telephones already exist.

A dispatch from Seattle, Wash., states that Gen. A. W. Greely, chief of the Army Signal Service, returned from Alaska on the steamship Ohio which arrived in port on September 28. The steamship Orizaba, engaged in laying a Government cable between Nome and St. Michael's, went aground on an unchartered reef near the latter place September 17. Gen. Greely was on board at the time, and says the vessel will be saved unless a sudden storm causes it to break up. The steamship Senator started at once from Nome to take off the crew and cargo including the Government cable. The laying of the cable will be postponed until next season. The Ohio brought 500 passengers.

The air ship designed by Count Zeppelin in Germany, and which was about to be given another trial, has met with an accident. The chains which supported the air ship broke a few days ago, with the result that the ponderous mass, weighing about nine tons, fell with a crash. Several ribs were badly bent, and will have to be replaced before a test of the ship's flying powers can be made.

Mr. Cowper-Coles, the electro-metallurgist, has worked out a system for drilling and slotting metals, principally iron, by means of electrolysis. A jet of an electrolyte, either dilute sulphuric acid or a solution of common salt, is caused to impinge on the plate or other object to be drilled. The plate or other object is made the anode of an electric circuit, the nozzle from which the jet flows forming the cathode, and a current of electricity being passed through from the plate to the nozzle. The plate is, says the "Colliery Guardian," London, worn away where the jet impinges on it, just as the anode, the silver or copper plate, is worn away in an electro-plating bath. The arrangement forms, in fact, an electrolytic bath, the containing vessel being the air surrounding the jet. As the apparatus in its simplest form is found not to drill or slot very accurately, the inventor has slightly modified it. In his later apparatus he has the nozzle brought right up against the plate, but separated from it by an india-rubber washer, which determines the size and shape of the hole. A small needle point also is arranged to form the negative electrode, the cathode, the powder from the hole or the slot collecting on it.

One of the most interesting features of the extension of the electric lines of the Bay Counties Power Company to Oakland, Cal., will be the cables suspended over the waters of Carquinez Straits. Tall steel towers are now being built and in a short time four cables will be hung from them, carrying a powerful electric current, which will be used on some of the street railway systems in Oakland. The main power station of the Bay Counties Power Company is situated in the canyon of the Yuba River, somewhat over 140 miles from Oakland, and men are now at work over the entire distance constructing the first of two lines. Each line consists of three wires, and it is necessary to construct two lines, so that in case of accident to one line the other may be used.

According to the London "Times" a novel machine gun has been invented by Mr. James Judge, an engineer at New Castle-on-Tyne. The gun is a patent centrifugal quick-firing machine gun; it is five feet high and weighs about five hundred weight. It is intended for battleship, earthworks and garrison purposes. The motive power is electricity transmitted to a motor attached to the side of the gun. The motor causes a disk to revolve at a very high rate of speed. The bullets, which are introduced into the interior of the disk at the axle, travel along curves in the interior to the circumference and are there impelled through a barrel. It is claimed that this disk will rotate, under the influence of the motor, at the rate of 12,000 revolutions per minute, and will eject shots from the muzzle of the gun with an initial velocity of 2,000 feet per second. One of the chief characteristics of the gun is that it will maintain a continuous fire. If necessary, a shot may be discharged at every half revolution, but in practice one shot every fourth revolution will be found sufficient. The bullets are spherical and measure 3-16 inch in diameter. The following are the results of the tests already made with the gun: 18,000 rounds of shots at the rate of 3,000 a minute have been discharged from the gun. These shots consisted of nickel, steel, some of brass (as used in France), lead and chilled metal.

Major T. B. Mott, U. S. A., who represented the United States at the recent French manœuvres, is reported as making the following statement on the utility of automobiles in the army: "The manœuvres proved extremely interesting and instructive. From several points of view the extensive use of auto-cars was a most striking innovation, and the results attained have fully justified the claim for their practical utility in European warfare. They did excellent work, enabling the generals and their messengers to cover great distances in a few hours. Auto-traction cars, moreover, immensely facilitated the work of the commissariat department, each drawing six or seven cars heavily laden with provisions. They have undoubtedly come to stay. I examined this question of military automobiles, however, from the American standpoint, and, while fully appreciating the enormous service they render to the armies of Europe, where the highways are level and well built, and the distances comparatively small, I do not believe they would be of sufficient value on the rough American roads and over enormous tracts of country as in the United States, to justify the heavy expense of their introduction and maintenance in the American army."

In 1894 the Caborundum Company at Niagara Falls commenced the manufacture of carborundum on a really commercial scale by the use of an electrical current of 150 horse-power, which gave a production of 100,000 lbs. of carborundum per year; in 1895 the company built its factory at Niagara Falls, and 1896 commenced the use of 1,000 electrical horse-power. In 1899 this was increased to 2,000 horse-power, the production of carborundum for that year amounted to 1,742,000 lbs. On January 1, 1900, the company had in operation fourteen furnaces. The scale and the character of the sale of carborundum has changed from a measurement by the carat at $600 per lb. in 1892 to the measurement by the carload at 10 cents per lb. in 1899. The total sales of carborundum in 1899 amounted, to 2,018,000 lbs., says the "Mining and Scientific Press." Besides the varied and commercial uses of carborundum, it is now becoming of interest to metallurgists in other fields, notably in its substitution for ferrosilicon in steel manufacture.

It is stated in the French press that a proposition by the Société Electrotechnique of Vienna, Austria, to hold an electrical exhibition in that town in 1903 has been received with great favor. Committees are already being formed, and numerous inquiries have been made as to the details of the exhibition. Everything apparently is to be done to make it a success, and the work of organization has already commenced.

A new arrangement has been inaugurated in connection with the Berlin telephone service, by means of which a subscriber can obtain a time signal every morning at nine o'clock. Subscribers wishing to receive the benefits of this system must pay an extra subsription of $2.50 per annum, and must see that their telephone is not in use at about the time the signal is expected. The signal is given to all subscribers precisely at nine o'clock by their bells ringing, and continuing to do so for about one minute.

Figures compiled by the Treasury Department give an excellent idea of the extent to which American electrical manufacturers are invading the foreign markets. During the eight months ending August of the present year, the exports of electrical machinery reached the enormous valuation of $3,590,419 as against a value of $1,828,048 for the same period of last year. The value of the exports of instruments and apparatus for scientific purposes, including telegraph, telephone and other electric apparatus, increased from $3,610,966 during the eight months of 1899 to $4,171,561 for the same period of 1900.

STORAGE BATTERY—ITS USE ON SMALL ROADS.*

BY B. B. VAN NOSTRAND.

The application of storage batteries to the generating system of large electric roads has been described by many engineers in a variety of ways, so that an impression has been left upon many minds that it is only with these larger systems that the battery scheme is feasible. This idea is incorrect, and I think that the following description of the equipment and operation of the Peekskill Lighting and Railroad Company will bear me out in the statement. In the description of this road we shall see conditions that apply in a general way to most small lines.

This road was placed in operation in June, 1899, since which time it has been running without any interruption except momentary stops caused by the circuit breakers flying out. Beginning at the station of the New York Central Railroad, which is at the western edge of the town, near the Hudson River, the road proceeds in a practically straight line through the center of the town and on to Lake Mohegan —a total distance of 4½ miles. The road is an exceptionally hilly one, in fact the fairly level portions are the exception, and are never more than 1,600 feet long. Beginning at the New York station terminus, the road, as far as grades are concerned, is about as follows: Starting into town, there is 1,000 feet of 7½ per cent. grade—with a small portion (say 20 feet), where it reaches 9 per cent. For a distance of about 4,000 feet beyond this, there is a gradual grade, varying from 5½ per cent to 2 per cent. terminated by 300 feet, of 5½ per cent. to 7½ per cent. At the top of this is a short level, leading into a 2,000 feet 2 per cent. incline, followed by 1,600 feet, varying from 4½ per cent. to 8½ per cent., which is in turn followed by 2,000 feet of 3½ per cent. up-grade. There is after this a depression, represented by 1,400 feet of down-grade, varying from 6.8 per cent. to nothing, which, after passing into a short level rises by 1,400 feet up-grade with a maximum of 4.6 per cent., to another short level. Then follows another down-grade of about 1,800 feet, varying between 8 per cent. and 2 per cent. This is followed by 1,600 feet of level—terminated by 300 feet of 8 per cent. After this is 1,000 feet of level, passing into a short down-grade of 6 per cent., 1,300 feet of level is after this, passing into 2,000 feet of 7½ per cent. The final portion to the end of the road is about 800 feet level.

This entire line of single track, with four turnouts, 56-lb. T-rails are used throughout, these being laid in the usual manner.

There is a single-track branch 4,000 feet long extending from the New York Central station north to the State Camp Ferry. This operates but one month of the year, at which time two cars are in service.

The overhead construction of the system is simple—consisting of 00 trolley throughout, with 0000 feeder, extending to within ½ mile of the lake end and 1,000 feet from the station end. The branch has no feeder. The 0000 feeder is tapped at regular distances throughout its length.

The apparatus for operating the road consists of one 60-kw Edison bipolar 575-volt, 880 r.p.m. generator, belted to a horizontal 13-in. x 12-in. Armington & Sims simple engine, the horse-power of which is about 100, at 275 r.p.m. Belted to this same engine, in tandem with the dynamo, is a four pole differential booster, which is used to render the charging and discharging of the battery automatic.

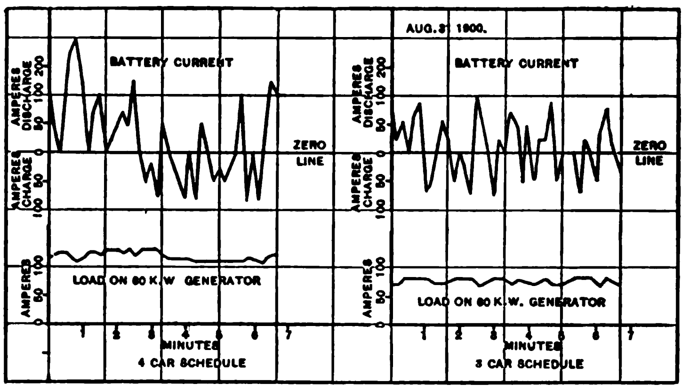
There is another unit consisting of a Westinghouse 120 kw, multipolar 625 r. p. m. generator, belted to a vertical 14 in. and 24 in. x 14 in. Westinghouse compound engine of 200 hp. capacity. It may be added here that this generator is rarely used, and that only when the road is unusually heavy—such as occur on holidays and warm Sunday afternoons. The same engine which operates this generator is also belted to one of the alternators for incandescent lighting. It may be well to note that in addition to the above engines there are three other engines which operate the remaining light machines. These, of course, have nothing to do with the railway system. In the boiler room are three 80 hp. and 100 hp. horizontal return tubular boilers, carrying steam at 105 lbs. pressure. During the summer months two of the 80 hp. boilers are sufficient to run the entire plant—though three become necessary in winter.

The battery, which is in the simple wooden shed next the boiler room, consists of 262 type F-9 chloride accumulator cells. Each cell is comprised of nine plates, 10½ ins. square, suspended in glass jars of sufficient size to enable the capacity to be increased in future by the addition of more plates. Each cell is mounted upon a wooden tray, filled with sand, to ensure an even foundation for the jar. These trays rest in turn upon glass insulators, supported by a wooden battery rack. On full charge the battery has a maximum rated capacity of 160 amperes for short periods. As a matter of fact, however, it is often called upon to discharge at a considerably higher rate than this, 250 amperes being called for momentarily.

During the summer season three cars are run from 6 A.M. to 12 M. Two of these run through Peekskill as far as the car house at the eastern edge of the town. The other car runs through the town and on to Lake Mohegan. This gives a twelve-minute schedule in town, and forty-eight minutes through to the lake. In the afternoon and evening four cars are run, giving a twelve minute schedule in town, and twenty-four minutes through to the lake. On holidays, etc., five cars are run, all going through—thus maintaining a twelve-minute schedule throughout the run.

Having gained a fair idea of the nature of the system, we will pass to the results obtained in the station.

The point of first importance is the remarkable constancy of the load upon the generator, and the correlated fact that the 60-kw machine is all that is necessary to operate the road, except when running the five-car schedule. The curve marked No. 1, in the engraving, will explain this. This shows the results of ten-second readings, taken upon the battery and generator during a short portion of a four-car run. The total line current is, of course, the summation of these two. It is seen that this total current fluctuates between 25 amps. and 310 amps., and that the generator runs along at practically full and constant load—the battery assuming the fluctuations above and below this. Curve No. 2 shows the same results for a three-car run. Here the average or generator load is lower (about 75 amps.), and the line fluctuations from 0 amps. to 170 amps. The practical good of this is evident. It means that a 60-kw. machine is running instead of 180 kw., which would be required were the battery not in service. In other words, although



No. 1. No. 2.

the load fluctuates from almost nothing to 180 kw., the average is in the neighborhood of 60 kw., and it is this average only which falls upon the generator and engine. The remarkable evenness of the load upon the generator produced by the operation of a storage battery is shown very nicely by the fact that we are operating our 120-kw. railway machine and one of the alternators for our electric lights from the same engine. Ordinarily this would produce a very serious flickering in the lights, but in our case it is impossible to detect the slightest change in the brilliancy of the lamps, although the railway may be fluctuating between its widest limits. I have not had an opportunity to test the coal saving produced by this arrangement, but I am confident from my observations that it is sufficient to pay a good return upon the battery investment over and above the interest and depreciation charges.

The increased economy of a small unit operating at a full and constant load above that of one three times the size, but doing the same work under highly fluctuating conditions, is such as to warrant this assumption.

It would be difficult to increase the simplicity of operation in this plant. After the original adjustment, the apparatus has worked together without the slightest difficulty. We have a generating unit operating under electric lighting conditions, due to the fact that the battery removes from the systems all sudden overloads, and the strain thus removed from the minds of those in charge is in its effect almost as valuable as this latter consideration.

In other ways the battery is valuable. A great many times it has been necessary to shut down the small engine suddenly from some mishap. During the eight or ten minutes neces-

*Paper read before the New York State Street Railway Association, held at Buffalo, Sept. 18, 1900.

Digitized by Google

sary to get the other unit into operation the battery has carried the entire load.

Then, too, it is often desirable to run a car for some special occasion very late at night. At such times the generator is shut down and the battery thrown across the line.

In conclusion, I may state that the battery has given us absolutely no trouble since its installation, and the daily labor for its proper care does not average more than one-half hour. In fact, about all the work required is that of taking voltmeter and hydrometer readings upon the individual cells once each week.

THE BRITISH ASSOCIATION.

[The following are abstracts of papers read at the meeting of the British Association for the Advancement of Science held at Bradford, Eng., Sept. 8, 1900.—Ed.]

WIRELESS TELEPHONY.

BY SIR WILLIAM HENRY PREECE, K.C.B.

The first experiments in this direction were made in the month of February, 1894, across Loch Ness, in the Highlands. On that occasion trials were made to determine the laws governing the transmission of Morse signals by my electro-magnetic method of wireless telegraphy, which has formed the subject of frequent reports to this section since 1884. Two parallel wires well earthed were taken, one on each side of the lake, and arrangements were made by means of which the wires could be systematically shortened, with a view of ascertaining the minimum length necessary to record satisfactory signals. It occurred to Mr. Gavey, who was experimenting, to compare telephonic with telegraphic signals, i. e, to ascertain whether articulate speech could be maintained under the same conditions as Morse signaling. The trials showed that it was then possible to exchange speech across the loch at an average distance of 1¼ miles between the parallel wires, when the length of the wires themselves was reduced to four miles on each side of the water.

What led to this train of thought was the fact that, although the volume of a telegraphic current was immensely greater than that of a telephonic current, whenever through want of balance in a loop disturbance was evident, then telephonic cross talk was also manifest. In other words a weak telephonic current was apparently as powerful a disturber as a strong telegraphic one.

The sensation created in 1897 by Mr. Marconi's application of Hertzian waves, distracted attention from the more practical, simpler and older method. Mr. Evershed and Prof. Oliver Lodge had in the meantime much advanced the system by introducing admirable call systems.

In 1899, I conducted some careful experiments on the Menai Straits, which determined the fact that the maximum effects are produced when the parallel wires are terminated by earth plates in the sea itself. It became quite evident that the ordinary inductive effects are much enhanced by conductive effects through the water, and that in consequence shorter wires are practical. No special apparatus seems necessary. The ordinary telephonic transmitters and receivers were used.

It became desirable to establish communication between the islands or rocks known as the Skerries, and the mainland of Anglesey, and it was determined to do this by means of wireless telephony. The lighthouse at the Skerries was wanted to be in communication with the coast-guard station at Cemlyn, which is connected with the Postoffice system, The bottom of the Channel is too rough, and the currents too violent for a cable. A wire 750 yards in length was therefore erected along the Skerries, and on the mainland one of 3¼ miles from a point opposite the Skerries to Cemlyn. Each line terminates by an earth-plate in the sea. The average distance between the parallel portions of the two wires is 2.8 miles. Telephonic communication is readily maintained and the service is a good one. Lodge's call system will be used.

No experiments have yet been made with ships, but it would appear simple to speak by telephone between ship and ship, or between ship and shore, to considerable distances across space by means of a circuit formed of copper wire terminating at each end of the ship in the sea, passing over the topmast and using simple telephones.

MANCHESTER AND LIVERPOOL RAILWAY—BRAKES AND SIGNALS.

BY F. J. BEHR.

Brakes and signals are so intimately connected that the one cannot be treated separately from the other.

The most perfect condition under which a railway could be worked, would be that in which both brakes and signals could be dispensed with, therefore it follows that the fewer the occasions for using either, the better.

Now as to brakes, there is a limitation of their application, which, demands not so much on the mechanical appliances themselves as on the endurance of the human bodies in the trains. It was stated by an eminent railway official that with the Westinghouse brake, a train traveling at 60 miles an hour could be stopped, as an emergency brake, within 360 yards without inflicting too great a shock on the passengers. In the same way, a train traveling at 110 miles an hour could be stopped within 500 yards, and probably in a shorter distance, as in the latter case electrical means are at hand, such as the reversal of the motors, so as to turn them into dynamos. More rapid stoppage could only be made with great discomfort to the passengers. Now in the ordinary way of working our railways at present, there are many occasions in which it might be important to stop the train as rapidly as possible. For instance, if a train in front should be seen, or some shunting operations were not completed, or others too many to enumerate, but no brake, however powerful would be of the slightest use to day to avoid a sudden obstacle, such as a stone placed on the rail or a broken rail, for it is impossible for the driver to be aware of such obstacles until he is practically upon them. For these cases of great emergency, therefore, the stoppage at 300, or 200 or even 100 yards is quite useless.

What I wish to show now is that on the proposed high-speed electrical railways, though it is quite possible to brake the train within less than 500 yards, it never can be necessary to bring it to a standstill at even a much longer distance.

On the proposed railway there are no level crossings, no switches, no shunting operations, and in fact nothing that will require the train to be brought to a standstill, except in the event that a preceding train should break down. Besides this one case, the brakes can only be used for stopping as you approach the stations. A broken rail offers no danger in this case whatever, for the train would run over it without any danger or difficulty. This can easily be shown by carefully considering the relative position of the wheels in the carriages to the rails over which they travel.

I now, therefore, have only to explain the manner in which it is arranged that the driver of each train shall be informed of the possible stoppage of the train in front of him.

No second train will leave the station at Manchester or Liverpool until the first has reached Warrington, a distance of just 17 miles.

We subdivide the line for the purpose of signaling into eight sections of 4.3 miles each. As trains leave Manchester station a danger signal is put up automatically at that station, a second similar danger signal is put up in the same way at 4.3 miles off, the first remaining at danger. The train travels on until it reaches 8.6 miles, when it puts up a third danger signal, and simultaneously the signal is lowered at Manchester or Liverpool station, so that the second train can leave when the time comes.

Now, we will assume that the first train has met with an accident after passing point 8.6 miles, the second train would travel at a higher speed right on, but when it passes point 4.3 miles, the danger signal at that point not having been removed by the first train, as this never reached point 13 miles, the driver of the second train would be informed that the first train had met with an accident beyond 8.6 miles and threfore that he had to slow down, but that for such lowering of his speed he had a clear run of over four miles. Therefore, there could be no difficulty in any case to stop even without using the brake at all, by simply cutting off the current.

Whenever a train passes over a point where the danger signal is put up this is also produced, either electrically or mechanically, by a very simple and inexpensive contrivance in the cabin of the electrician, so that he should be perfectly able to see it without difficulty even if there was a thick fog

Under these conditions of traveling it seems, therefore, superfluous to have any emergency brakes, and though we shall be able to stop the trains within 500 yards, no case can be imagined in which it would be useful or necessary to resort to such a stoppage.

A six minutes' service of trains can be established without any alteration in the proposed arrangement, and if a three minutes' service was required, the blocks would have to be reduced to two mile sections giving a clear run of two miles in case of a breakdown.

A COMBINATION INTEGRATING WATTMETER AND MAXIMUM DEMAND INDICATOR.

BY T. BARKER.

The paper fully sets forth the advantages of the maximum demand system of charging for the supply of electricity, and describes a new meter—the invention of Messrs. Barker and Ewing—to be used for this purpose. The paper was illustrated by diagrams, and examples of the meter were exhibited.

In charging for the supply of electricity it has become usual to make a distinction in the prices charged to those consumers who use a few lights for many hours per day, and those who use many lights for an hour or less, for, although at the end of the year the number of

Digitized by Google

units consumed may be the same in both cases, the cost to the company or corporation in machinery, mains, and every other charge will be in the ratio of the number of lamps lighted at one time. The consumer who uses a few lamps for many hours should be charged at a less rate per unit in view of the smaller capital expenditure which his supply involves.

The late Dr. Hopkinson advocated a system which takes account of this consideration in arriving at the fair price to be charged for current. In the system in question, now known as the "Maximum Demand System," the total quantity of electricity consumed in six months is measured in the usual way, and the greatest rate at which the consumer has been taking current is also recorded. If the consumer in the six months' period takes a smaller total than would correspond to one hour a day at the greatest rate of demand he is charged the full price per unit, but if the total consumption exceeds this he is charged a reduced rate for each unit in excess.

The system has been used with marked success in some seventy-two towns. It has improved the load factor, and has enabled a large number of additional units to be sold without increase of station plant or mains. Until the introduction of Barker and Ewing's demand indicator it was necessary to use two meters —one to record the total number of units taken by the consumer and the other to show his maximum rate of demand.

The Barker and Ewing indicator forms an integral part of the ordinary meter, and absorbs no energy; it further records watts and not amperes. With an alternating supply it shows actual watts and not apparent watts, an important difference in the case of motors and arc-lamps. It is not affected by any ordinary short circuit, its time lag being sufficient to prevent it coming into action. The indicator may be used to show the actual rate of demand at any instant in place of recording the maximum rate of demand. In this form it is specially useful in switchboard instruments, showing the attendant the rate at which electric energy is passing through a feeder or is supplied from a dynamo at any instant. The meter also serves at the same time to integrate the total amount which has passed through that particular feeder or machine.

A Swiss Power Transmission Scheme.

A recent issue of the "Schweizerischen Bauzeitung" describes an interesting scheme for supplying Lausanne, Switzerland, with electric current for lighting and power purposes. The most noteworthy feature in connection with the undertaking is that the energy will be transmitted in the form of high-pressure continuous current over a distance of 56 km., and afterwards distributed in the form of three-phase current to consumers in Lausanne. The generating station will be situated near St. Maurice, in the upper valley of the Rhone. At the point selected the available fall of water varies between 34.5m. and 36m., which yields a minimum of 6,000 hp. while during 10 full months of the year 14,000 hp. may be obtained. The initial installment of plant will comprise five turbines with horizontal shafts, each capable of developing 1,000 effective horse-power when running at 300 revolutions per minute. The constant current generated will be conveyed by means of two bare conductors of each 150 mm. square sectional area to Lausanne.

MISTAKES IN THE RATING OF INCANDESCENT LAMPS.*

BY ARTHUR J. ROWLAND.

A 16 candle-power lamp is such a common article of commerce and in such general use that we all recognize it when we see it, or think we do, either by the size of its bulb or the length of the filament, or both. Very few people go beyond such mechanical identification except for the extra assurance they gain by a look at the manufacturer's label. Some, indeed, presume to tell that a lamp is of a given candle-power by looking at the brightness of its filament or by considering the general lighting of a room; but it need scarcely be said that an estimate formed by such a method is utterly worthless, since one is too much influenced by contrasts in brightness, or deceived by the temperature at which a given filament is burned, to really tell anything at all about the candle-power.

The importance of exact knowledge of the candle-power of incandescent lamps is at last being recognized among lamp users generally, One of the signs of this in the present times is the great number of photometers recently set up and used outside of laboratories. Certain standard measurements are made with these, which are good so far as they go, but commonly many important things are quite passed by unnoticed. Not only should the user of incandescent lamps want to know that the lamps he buys really have the candle-power marked on them, and that they maintain their candle-power properly as they grow old in service, but he ought to know and fully understand a number of other things regarding the real candle-power and watts per candle-power of the lamps he uses. Some of these seem to have quite escaped notice, and their importance is so great as to merit careful consideration.

WHAT A 16 CANDLE-POWER LAMP OUGHT TO BE.

Let us first inquire into just what a 16 candle-power lamp ought to be. That it should be one which gives a light equal to that of 16 candles in the direction in which the light is useful seems a natural and fair definition. A little careful observation of lamps as they are installed shows that at least 85 to 90 per cent. of those used are put in place with base upward, or tipped end downward, and it is the light which comes from this tipped end of the lamp which is useful. In cases where the lamp is installed in a different position, either the lamp is subordinated to some artistic feature of the electrolier, or the lamp is installed "side on" to better keep it out of the way. So it comes that the light we ought really to want to know about, the light we ought to measure, is that coming out of the end of the lamp. Or at least it is sure that, if we call the axis of the lamp a line through it from the middle of the base up to the sealed-off tip, the light of value is that coming into space below a plane perpendicular to the axis, half way along its length. We can never use more light than this, since for satisfactory lighting the sources must be above us, and in real service we make use of much less, as will be presently shown. Should we take the average candle-power of all the light rays into space below the imaginary plane just defined, this would be called the mean hemispherical candle-power, just as the average candle-power of all the light rays given by the lamp in every direction is called the mean spherical candle-power.

THE IMPORTANCE OF THE LIGHT FROM THE TIPPED END.

The placing of lights is to-day being made much more intelligently than by the old rules of so many 16 candle-power lamps per 100 square feet of floor surface, or per 100 cubic feet of room to be lighted. Some certain amount of illumination is now striven for, and a proper distribution of light rather than of lights is sought.

In a great deal of lighting one tries intentionally to give illumination concentrated about particular points. For example, in lighting a library it is the library table which is to be brightly lighted; other parts of the room need little more than the scattered rays otherwise useless, which reach them directly from the light source or after reflection. The light rays in poor planes and the reflected light which comes from the table, the walls and objects in the room, though contributing little to the important light, serve to break up shadows and produce diffusion. Almost the same thing would be true of the lighting of a bedroom, where the light should be concentrated about the bureau or dressing table.

In quite a different sort of lighting, still the same things hold true. Take the lighting of a factory or mill for example. The light must be on the machines or work, and be very good there. That which gives the room its general lighting is waste light from the light sources. To light the whole room as brightly as the machines would be too costly to be practical. For such lighting let us consider what rays are useful and what rays waste light. If the lamp hangs directly above the thing to be lighted, and its area be not more than 5 x 5 feet, no rays of light beyond 30° from the axis of the lamp will be useful, and the higher the lamp is hung, the less the angle in which the useful light is found.

A second sort of lighting is that in which a uniform distribution of light is required, as in concert halls. or auditoriums of various sorts, and in shops for the sale of merchandise. A fundamental principle in this class of lighting is to use many sources of small candle-power each, all so placed that the light from them is directed downward, with perhaps a little diffused side light to break up the shadows, especially in small interiors. The lighting engineer is forced to use single lamps to procure this, except in large rooms, and they are nearly always installed base upward. The light from the tipped end produces the light of value.

A third sort of lighting is for decorative purposes, but that is so very especial and foreign to considerations of candle-power at all in most instances as to merit no consideration here.

The light below the lamp—that from the tipped end—is then the important and useful light in all practical cases. This is true, too, not only from the specific cases cited, but where large electroliers with many lights are used as well; for in such cases the lamps are usually flared out, with axes at some angle approaching 45°, in which case high candle-power from the tipped end and low from the sides of the lamp would contribute to a good even illumination of the room.

The importance of procuring high candle-power below the lamp has been recognized a long time. But what expensive and roundabout methods have been taken to procure it! It is very common to use reflectors to increase

* Paper read at a meeting of the Franklin Institute, Philadelphia, Pa., September 19, 1900.

Digitized by Google

the amount of light in the direction below the lamps. While reflectors have their place in lighting, and an important one, too, for most purposes they are exceedingly poor and are used in ignorance of the effects they produce, or because no better device for light distribution can be had. No matter whether the reflector covers the lamp or not, no matter whether it is of porcelain, a glass mirror, or a polished metal surface, it inevitably cuts the light off absolutely in some directions and so directs it in others as to produce sharp shadows and brilliant lighting contrasts. In satisfactory lighting contrasts of light and shade are always avoided, and by producing diffusion most shadows are lost. Other devices, like McCreary shades and specially shaped incandescent lamps having a reflector incorporated with the lamp, have faults precisely the same as reflectors. Holophanes, with their prismatic and accurately formed surfaces, turn the light downward and at the same time diffuse it by refraction, so that on all artificial lights the distribution of the light and the lighting therefore is improved by their use. A holophane gives a redistribution of light immeasurably better than a reflector always. If an incandescent lamp is installed base down, holophanes or reflectors must be used on it or the lamp be valueless in supplying really useful light.

The common use of such devices is evidence that the ordinary incandescent lamp does not give as much light below it as is required there. Is there, then, a bad light distribution from them? An examination of modern lamps will tell us.

FILAMENT TYPES AND CANDLE-POWER DISTRIBUTION.

There are five different types of filament in use to-day by various prominent lamp manufacturers, and in most cases a filament type indicates the product of a certain manufacturer who has adopted that as the one used in his standard lamps. These typical filaments are enough different from each other to show interesting individuality. I have classed them as follows:

(a) Straight U-shaped filament; a type rapidly passing altogether out of use.

(b) Single curl filament; a type much used, having a circular loop in the filament midway of its length. This type was originally designed to render filaments stiffer and less liable to bend without an anchor, and also to shorten the lamp bulb. It was found to give a better distribution of light than type a.

(c) Long curl anchored filament; a type differing from type b in that the loop is long in the direction of the lamp axis and is anchored to the part of the lamp where the leading-in wires pass through the glass.

(d) Double filament; a type which uses two filaments like type a, set so the current passes through them in series, the filaments being in planes approximately parallel.

(e) Double coil filament; a type like b, except that there are two turns in the coil instead of one.

Besides being typical in the matter of general form, the light distribution observed from these various filaments is also typical. It is, however, considerably influenced by the exact relation of different dimensions in the filament itself used by particular firms; as, for example, the diameter of a coil or the spread of the filament shanks. Results below are therefore departed from somewhat if different makes of lamps had been used in the tests.

Fig. 1 shows average candle-power values from lamps of each of the different types. The arrows indicate the direction from which the candle-power was measured and the number gives the candle-power. These values are true averages of the types shown. In the averages struck no "freak" lamps were included. The five types are each represented by the product of some prominent lamp-maker. All the lamps are rated 16 candle-power, all were in the standard bulb used by the manufacturer of a type, and, as it happened, all were 3.5 watt 110-volt lamps. A careful inspection of the figure shows one that the form of filament has a most important relation to the candle-power distribution, as of course it must since the candle-power delivered in a given direction is determined almost wholly by the amount of filament length visible from that direction. A filament of type a shows only the end of the U when one looks in at the tip, and so the candle-power must be low, even if the U be broad. A double filament must show low candle-power for the same reason; and if the filament loops are narrow and the legs of the filaments straight, as they were in the lamps of the make tested, the candle-power may be even lower out from the tipped end than for a filament of type a. A filament with a coil in it shows much more projected length when viewed from the lamp's end, and so gives comparatively high candle-power in that direction. We see, then, that a 16 candle-power lamp is very different in the candle-power it gives in various directions and very different in a given direction with difference in type of filament. That lamp which gives most useful light is undoubtedly the best. Hence there is no question but that the 16 candle-power lamp with filament of type e is a far better lamp for general lighting purposes than any other. It is almost beyond belief that this has escaped notice in all the years incandescent lamps have been made and used, and yet it has been so. I first had my own attention called to the matter by the Shelby Electric Company, for whom I was making some tests of candle-power. It is their lamps which show as type e. In an attempt to find whether in the past any one had attached importance to the light coming out from the tipped end, I have been surprised to note how, over and over this or that experimenter or lamp manufacturer has been on the verge of the discovery and then passed it by. One of the most recent cases I have noticed is that of a lamp manufacturer who advertised sign lamps with "all the light from the end," but seems never to have thought that this would be the right sort of lamp to use as his standard product.

Fig. 2 gives the relative amount of useful light from filaments of the different sorts, expressed in per cent. of the light given by the double coil filament (type e).

The Shelby lamp (type e) for which data is given was made tipless; that is, the sealing off after exhaustion was not done as usual at the tipped end. The gain in candle-power by omitting the tip, so far as tests which I have been able to make indicate, is about 12 per cent. The loss in tipped lamps is probably due to light absorbed through the thicker glass at the tip and partly to reflection and refraction of light into useless directions which otherwise might have been saved to be useful.

(a) Straight U-shaped filament.
(b) Single curl filament.
(c) Long coil anchored filament.
(d) Double filament.
(e) Double coil filament.

Showing average candle-power distribution from incandescent lamps of various types.

What folly it turns out to be to use special devices to turn the light downward when the lamp itself can have the filament constructed so as to give a proper light distribution. A design of filament for incandescent lamps so they will give large candle-power from the tipped end is second in importance only to satisfactory efficiency and maintained candle-power with fair average life.

Filament.	Light in Given Direction in Per Cent.	
	Vertically Downward	30° from Vertical.
Type e	100	100
" d	44.0	63.4
" c	63.7	72.4

ILLUMINATION BY LAMPS USING FILAMENTS OF DIFFERENT TYPES.

A large amount of light streaming from the end of the lamp is only useful if it produces a

Digitized by Google

proper illumination. In Fig. 3 is plotted the illumination of a level surface 5 feet below a 16 candle-power lamp of different makes, the distribution being shown one way out from the lamp only. A single representative lamp was taken of each of three important sorts and the candle-power as marked on the diagrams determined for the light given in each of the directions shown by the arrows. The illumination was then calculated in candle-feet, and this plotted vertically from the base line. The solid curved line bounding the shaded area runs through the points so found, and all vertical distances from the base line give the amount of illumination there. Some of the values found are marked. Thus, for the long curl

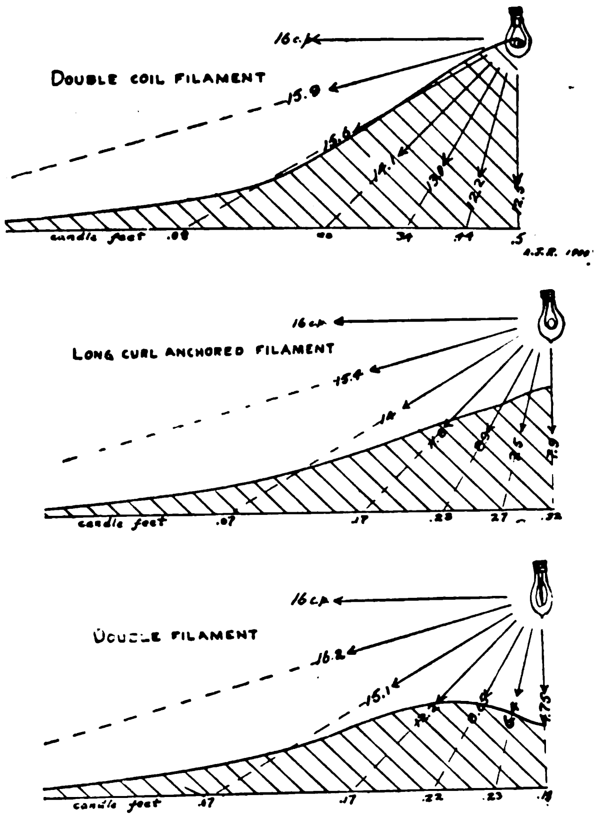

FIG. 3.
Illumination by filaments of different types.

anchored filament .32 of a candle-foot is procured at the surface illuminated by the ray giving 7.9 candle-power, .27 by the ray giving 7.5 candle-power, etc. The candle-foot unit is the common one; that is, an illumination of 1 candle-foot is that of a surface everywhere 1 foot distant from a light giving 1 candle-power in every direction. A surface 2 feet distant at every point from such a light source would have an illumination of ¼ of a candle-foot.

A first look at the diagrams would seem to indicate that the double filament lamp is best, since it gives more uniform illumination than either of the others. In any case, we need not concern ourselves with the light received from rays making an angle greater than 45° with the vertical; since up to this angle a circular area 10 feet in diameter, above the center of which the lamp hangs, is being lighted. Under the lamp the light is most valuable, and there we want to get most light. The double coil filament turns out, then, to be by far the best form. If in lighting an interior the lamps were hung separately and placed about 6 feet apart, the evenness of the illumination produced would be about the same for lamps having double coil filaments, or lamps having long curl anchored filaments; but the amount of illumination procured from double coil filaments would be so much greater that they are much to be preferred. We are assuming all along that 16 candle-power lamps, as the manufacturers call them, are in use. If lamps were placed 15 feet apart, the distribution of light with double filament lamps would be very good if an even distribution is desired; but the average illumination would be low.

It is interesting to notice, in these plots of illumination, that after the 45° ray is passed the value of all types of filaments is about the same; and it should be noted that the illumination procured is very small. An illumination of 1-10th of a candle-foot, for example, is that which one receives on a piece of paper held vertically more than 3 feet from an ordinary candle. Such light as passes out from a lamp most. Take a room in which the ceiling is only 12 feet high, in which a 16 candle-power lamp hangs 4 feet from the ceiling, and one finds that no rays from any lamp now made, passing out to reach the ceiling or wall above the horizontal plane through the lamp, will give an illumination of as much as .05 candle-feet on a surface 5 feet below the lamp, even on the assumption that the ceiling and wall are the best possible reflectors.

INFLUENCE OF FILAMENT FORM ON CANDLE-POWER.

A number of interesting matters connected with the distribution of light from lamps having filaments of the different types are shown in Figs. 4 to 8, inclusive. Each figure gives

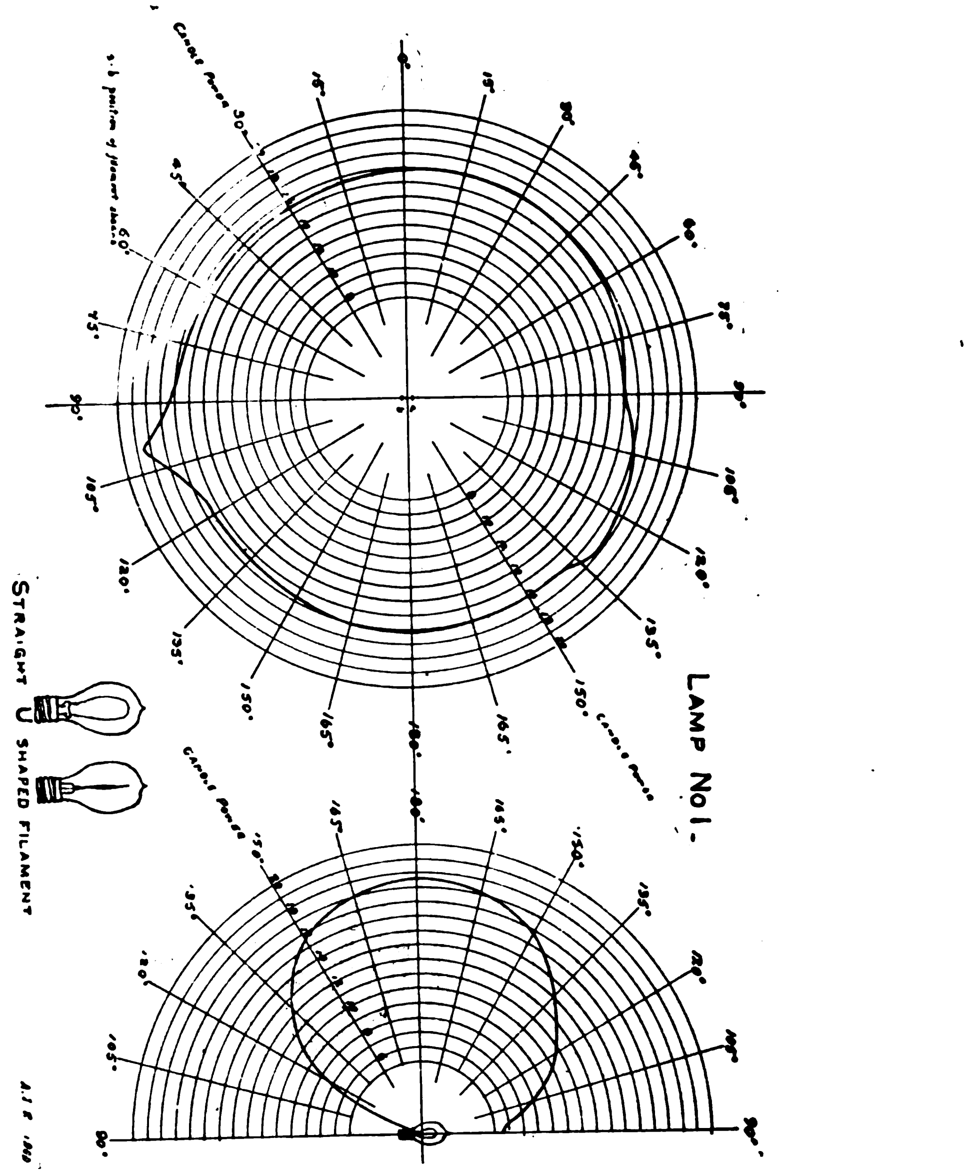

FIG. 4.

in directions nearly horizontal or above the horizontal plane is useless except it is reflected back to the surfaces to be lighted or contributes to the general illumination by dispelling the gloom of the upper parts of a room and by giving a diffused character to the light. While it has such value, it is rarely that one can afford to use much light this way. If light is useful after reflection, it must travel in long paths: so that even if it reaches points where it is useful, so little illumination is produced that direct light is much the best. A very white surface will not reflect more than 85 per cent. of the light which strikes it, while dark walls and ceilings and hangings reflect almost no light at all. The item of reflected light is then one of very uncertain amount at the results from a test of one lamp—a lamp chosen to represent the type because it was truly representative mechanically, and by check against other lamps was found to be representative in light distribution. The rough sketch of the lamp on each figure shows very nearly the actual shape of the filament whose candle power was measured. The left-hand sketch shows the lamp as it stood for measuring the horizontal candle-power at 0° and the right hand figure at 90°. In all the candle-power diagrams distance out radially from the center of the diagram to the heavy curves gives the candle-power in that particular radial direction. Thus, in the curve of horizontal distribution, if the lamp stood with axis vertical and one went around the lamp taking can-

dle-power of the light given in the direction toward him as he went on, these values of candle-power have been recorded and can be read off on the diagrams up to the heavy line. The same interpretation holds for the curves of vertical candle-power at the right of the figures.

All the lamps were kept at the voltage at which they give 16 candle-power on the basis of the manufacturer's rating. In the curves of horizontal distribution we see that lamp No. 1 with the straight U-shaped filament is quite uniform in candle-power all around. The candle power distribution of the long curl anchored filament (lamp No. 3) and the double

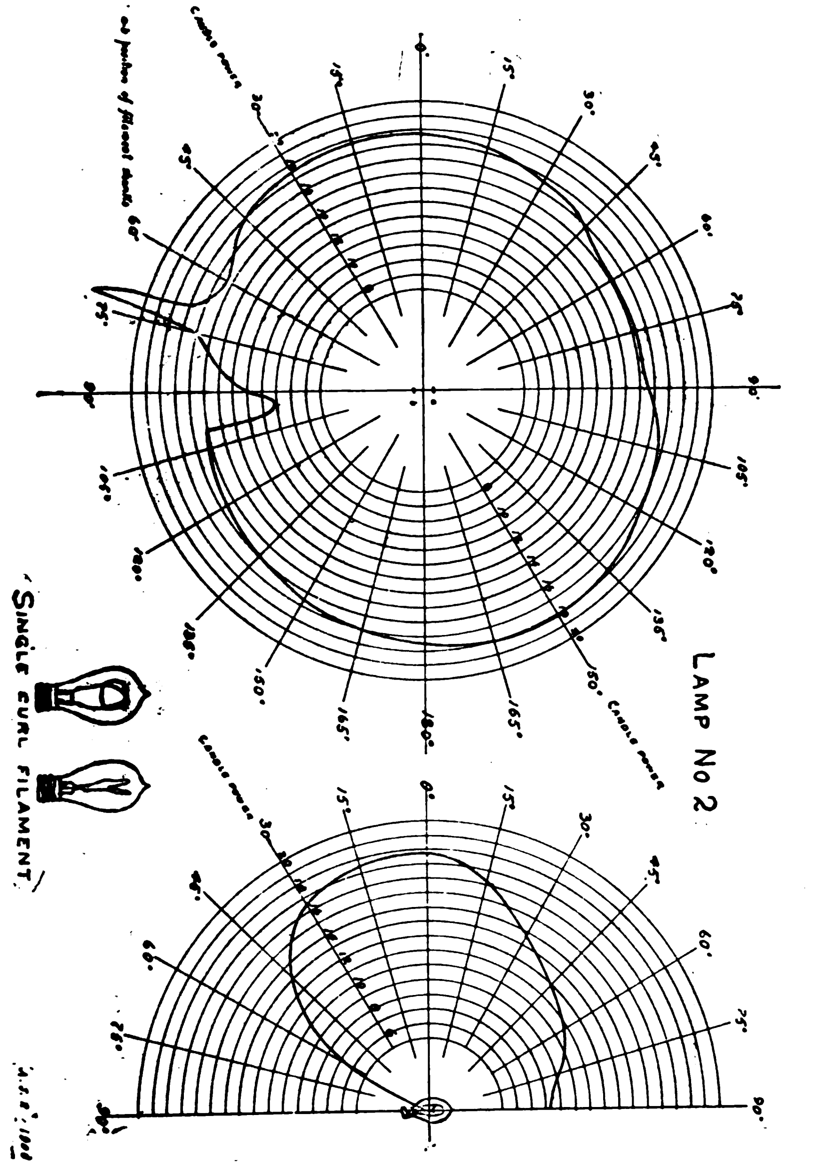

FIG. 5.

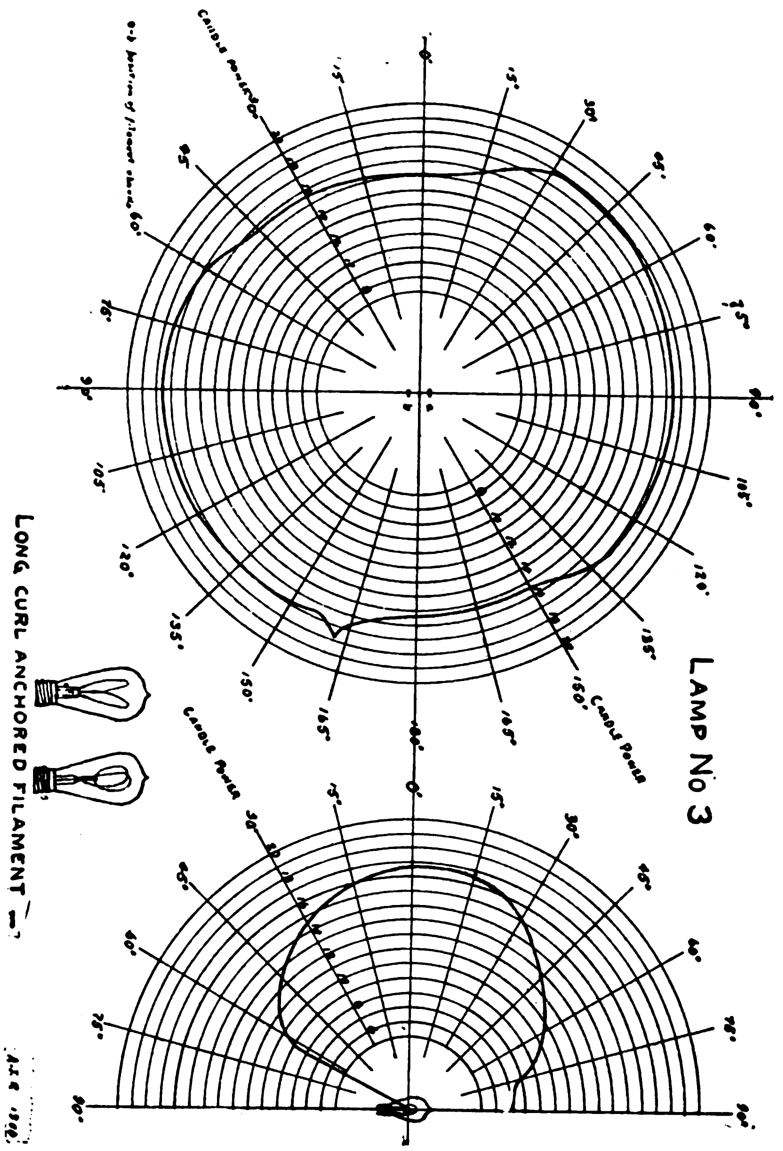

FIG. 6.

filament (lamp No. 4) are somewhat similar. The irregularity of the curves for lamps Nos. 2 and 5, coil filament types, is great. This is always distinctive of lamps of the sort. The striking irregularity at one point of the curve for lamp No. 2 is not abnormal. There are often two such breaks, one on each side of the lamp. The cause of this irregularity may be due to complex reflection and refraction of light due to varying thickness or curvature of the glass enclosure. It has not been investigated, I think. Since the manufacturer's rating is on the average or mean horizontal candle-power a lamp gives, the more uniform the candle-power curve of horizontal distribution, the more nearly perfect a lamp might be considered, I suppose. At least, this seems to explain design of the most recent filament forms.

But by far the most important distribution is that in a vertical plane. Here the great differences in candle-power procured from various filament forms show best. Look at the curves Lamps Nos. 1, 3, 4 are dreadfully deficient in light from the tipped end, and the candle-power of each falls off very rapidly as the 90° angle is approached.

How especially is this true of lamp No. 4, which, just as one comes to the direction from which the light is most important (between 75° and 90° at the tipped end), drops the candle-power down to less than five units. Most of the lamps, curiously enough, give most light in zones beyond the horizontal toward the base, where its usefulness is very problematical. This is true, too, of lamp No. 5, which maintains the candle-power it gives so well out toward the tipped end. It sends a good deal of light toward the base, but if we have a good light where it is useful, we must not criticise too severely the delivery of light where it has no especial value. The effect of the omission of the sealed-off tip on this lamp in helping up the candle-power at the end is well shown in the curve of vertical distribution for lamp No. 5, where from 75° to 90° the candle-power keeps up. This is due partly to the way the loops of the filament are spread, and partly to the omission of the tip.

WHAT IS A 16 CANDLE-POWER INCANDESCENT LAMP?

It does not take much consideration of these curves to satisfy one that a 16 candle-power lamp is not necessarily one which gives 16 candle-power where this much light is wanted. The candle power of incandescent lamps is determined really in a very empirical and arbitrary fashion. Most people seem to think it is as surely known as the watts used, and is as readily measured. But really it is about as vague and elusive a value as the candle-power of an arc lamp, for which it has facetiously been said that it gives 2,000 candle-power because at any street corner it delivers 500 candle-power in each of the four directions.

The common method of measuring candle-power in use by the manufacturers of incandescent lamps is to spin them at 180 revolutions per minute on a vertical axis and measure the average horizontal candle-power by a single reading. How this comes to be accepted as satisfactory, and what the status of candle-power measurement of incandescent lamps is, will be worth a little consideration right here.

When incandescent lamps first became commercial they were put into competition with gas lights and were made so they would measure 16 candle-power when placed in a photometer, precisely as gas lights had to be placed—base down, and the old U-shaped filament with a plane through the shanks of the U perpendicular to the photometer bar. Indeed, since photometers (except for purely scientific investigations) were used only for measuring the candle-power of illuminating gas, these

Digitized by Google

very photometers were used for the incandescent lamps; and methods for gas photometery were adopted as far as possible into their candle-power measurement. It was soon clear that some more complete sort of measurement ought to be made, and in 1885, in connection with important tests of incandescent lamps for their economic value, probably the most elaborate tests ever made, the Franklin Institute adopted a method of measuring the mean spherical candle-power which was really an empirical or arbitrary one, but gave as a result a candle-power value quite nearly the true average of all measurements when the lamp was viewed from all possible directions.*

The measurement of the mean spherical candle-power by the Franklin Institute method requires that at least between forty and fifty measurements on the photometer be made, and the average of thirty-eight determinations is taken to get the result. About two hours' time for two operators with a well equipped photometer laboratory is required for the measurement of one incandescent lamp, while the apparatus required, as supplied by instrument makers, is defective in that it does not enable satisfactory measurements of the light radiated in directions near the lamp base to be made. While, then, this method came near giving the real average candle-power of a lamp, it could not well be used by lamp manufacturers in rating their product, nor was it. Most of them rated their lamps by the candle-power measured when the lamp stands vertically with base downwards and the bar of the photometer points to some selected side of the lamp. Some attempts were made to use a constant number by which this reading of candle-power might be multiplied to give the mean spherical candle-power for a given type of lamp, but without success in commercial usage.

In recent years, lamps have been measured by their mean horizontal candle-power and so rated. To save time, the manufacturer has lamps standing in the position already described, but has them rotating when the candle-power is measured; 180 revolutions per minute is a common speed, and the voltage marked on the label is that required to give 16 candle-power when the lamp is so rotating. The user who checks the manufacturer's product as it is delivered to him must perforce use the same method.

The National Electric Light Convention, not satisfied with the uncertainty of the methods in use, and in order to procure uniformity of standards and practice in rating lamps appointed a committeee, who made a report at the convention in June, 1897, in which they say that the mean spherical candle-power is the only proper and fair value to consider in comparing lamps. The practical measurement of this is so difficult, however, that a simpler method was recommended whereby the average luminous output of the lamp might be measured. The proposed measurement was to be taken "in the direction inclined 45° to the axis of the lamp, while the lamp is revolving upon its axis, the distance of the lamp from the photometric screen to be regarded as the distance between the center of the axis of its bulb and the screen. This will furnish a fair approximation of the mean spherical candle-power and reduce the amount of labor in measurement to the minimum." Two revolutions per second or 120 revolutions per minute was recommended as a speed of rotation.

A year later, in June, 1898, the same committee made a further report telling of tests made, confirming the committee's suggestion of measurement at 45° of inclination and making the proper speed 200 to 250 revolutions per minute. The committee was continued and made another report at the last meeting of the convention, but altogether on other phases of the subject—photometers, standards of candle-power, etc. Here the matter rests. In spite of the official adoption of the report by the convention, manufacturers continue to rate their lamps by a measurement of mean horizontal candle-power with the lamps in rotation at

FIG. 9.

Candle-power of lamps with different forms of filaments.

In Fig. 9 I have set down a number of candle-power values for each of the five lamps of which some data was given in Figs. 4 to 8, inclusive. Each of these gives a value of candle-power by which the lamp might be called. The values were procured as follows: A lamp was set at 16 candle-power when rotating at 180 revolutions per minute with the lamp axis vertical, in the common arbitrary method, and for all measurements involved in the other tabulated values was held at that voltage. Values in line b were determined by taking the average of twelve readings as the lamp is turned, beginning with its standard position and at every succeeding 30°. Values in line c are computed from the curves in Figs. 4 to 8, which take account of all horizontal candle-power variations. The line of mean spherical candle-powers is computed by the Franklin Institute method. Notice how much less the real average is than the rated candle-power in each case and how this average compares with the rated value for each type of filament. Line e gives the candle-power these lamps should have been marked if rated by the National Electric Light Association's standard. The readings are not by a rotating socket, but averaged from readings made individually from the lamps tilted at the right angle. It will be noted that this agrees poorly with the value of mean spherical candle-power and bears no easy numerical relation to it. Line f of the mean hemispherical candle-power is to be compared with the spherical candle-power values, and this in turn with the line g, in which average candle power is included every ray of really useful light. Line h is set down for comparison and to mention later. With such an array of candle-power values for each lamp, what is its candle-power?

WHAT SHOULD A 16 CANDLE-POWER LAMP BE?

Earlier it has been pretty thoroughly explained that the only sensible candle-power by which to call an incandescent lamp is that which is useful in producing illumination at desired points. Such a method has never been used in marking incandescent lamps for sale. It is strange how precedent binds us in everything we do. Here in the matter of incandescent lamp candle-power we are all tied to methods of designation which look back to photometric methods used for gas burners. True, mean spherical candle-power and rotation methods are distinctively electrical, but they first came to be of importance because incandescent lamps are so commonly placed in positions impossible to gas burners; and the rotation methods are used simply to save time in measurement, one reading taking the place of a dozen. It has already been explained that mean spherical candle-power is an impossible measurement for commercial purposes. Rotation methods are poor, too. Not only does the speed of rotation affect the result procured, but some of the best modern lamps produce such a flicker at the car of the photometer when rotated at standard speed (180 revolutions) that not only is the making of an observation most trying to the eyes, but the observer can only make a rough guess for the position of his screen when a balance is obtained. A recent suggestion to choose such a speed for each lamp as just removes the flicker is impractical, also, for not only does it require an adjustment of speed with different lamps, but with many filaments high speed of rotation distorts the filament or even throws it against the glass, due to centrifugal forces brought into operation by the high speed.

What more rational, then, than to measure the lamp's candle-power looking in at the end? It is the light coming from the end which we make use of—which we are interested in. Then this is the light to measure, and that by which the lamp should be rated. Lamps measured thus are as comparable with each other as lamps measured any other way. The apparatus required to make the measurement would be very simple, for no rotating device would be required and the lamp need only be inserted in the socket without any care as to which side comes uppermost when its candle-power is determined, since the candle-power must always be read the same. Thus, readings of different observers would agree without respect to anything involved in the measurement, except the standards used and the personal element, which never can be eliminated. Such a radical change of method, however sensible the change, could not be made without the sanction and support of some of the large associations of electrical engineers. In the meantime, however, for eventually this method must certainly come to be used, all lamp users should, in addition to a measurement of candle-power in the conventional way to check up the lamps purchased, take a reading of the useful light out from the tip.

A 16 candle-power lamp should be one giving 16 candle-power from the tipped end. The horizontal candle-power might be considerably less and be irregular in different directions without altering the real value of the lamp. An ideal 16 candle-power lamp would perhaps be one which measures 16 candle-power from the tipped end, had 16 candle-power as the mean horizontal candle-power, and was of nearly 16 candle-power mean spherical. Such a lamp could be turned into any position in an electrolier and still give an illumination as good as before and as well distributed.

In most lighting, also, the end of the lamp which has been called the tipped end all along should be tipless. Hold a piece of white paper below an ordinary tipped lamp hung with the tip down, as it commonly is, and the reason is unnecessary to state. Variations in thickness of glass and shadow cast by the tip make lines of light and shade that spoil all real value of light procured.

Since the making of such lamps as these is doubtless but a choice of filament form and arrangement, let us hope it will not be long until there are some ideal lamps available commercially.

WHAT IS A 3.5-WATT LAMP?

So far no word as to the efficiency of lamps has been said. It does not directly affect the candle-power nor distribution of candle-power. All the lamps mentioned above, for instance, were 3.5-watt 16 candle-power lamps. But why are they 3.5 watts per candle-power? Each lamp used burned with a consumption of 56 watts. The efficiency or watts per candle-power is strikingly varied by the candle-power to which reference is made. In Fig. 10 are set down the efficiencies of each lamp of the five types, calculated on the basis of the candle-power values in Fig. 9. A 3.5 watt lamp turns out to be one which uses this much electric power per candle-power if this is reckoned at its highest value, the mean horizontal. What a terrible inefficiency these lamps have if we calculate the watts per candle-power from the useful light or the light from their tips!

Watts Based on Candle-Power, as stated.	Watts per Candle-Power. Single U-shaped Filament.	Single Curl Filament.	Long Curl Anchored Filament.	Double Filament.	Double Coil Filament.
k. At 180 revolutions with axis vertical	3.5	3.5	3.5	3.5	3.5

m. Mean with axis at 45°	5.33	4 66	4.79	4.66	4.00
n. Mean spherical.	4.40	4 15	4.07	4.23	4.07
o. Mean hemispherical	3.92	3.86	3.83	4.00	3.86
p. Mean within 30° of tip	6.44	5.44	6.44	7.09	5.14
q. From the tip	9.82	6.71	7.95	11.70	5.54

FIG. 10.

Watts per candle power of 16 candle-power incandescent lamps on basis of different candle-power ratings.

Lines p and q of Fig. 10 give this. Lamps 2 and 5 are the only ones whose efficiency reckoned in a rational way is at all reasonable. The lamps of Fig. 10 all were supposed to have the same average life and would not be very far different in maintenance of candle-power during life. If a lamp can be made which gives 16 candle-power out from the tip and burns at 5 watts per candle-power, we will have a lamp which is better than any now made. If its life is as good as the present 3.5 watt lamps, it would be a much better lamp than any we have now for all commercial usage. Keeping, however, to lamps now made, the table of Fig. 11 gives the relative cost of current per 16 candle-power of useful light (light from the end) from each of the five different filament types now made. The computation is on the basis of 12 cents per kilowatt hour for electrical energy, and the cost is per 500 hours of burning (the average life of a lamp).

Type of Filament.	Cost of current per 16 candle-power of useful light and per 500 hours' service.
Single U shaped	$9.43
Single curl	6.44
Long curl, anchored	7.62
Double	11.[illegible]0
Double coil, tipless	5.32
Double coil, 10 candle-power mean horizontal	$4.10

FIG. 11.

Since we only use electric current in incandescent lamps for the light we get, and since it is the cost of the light which is the vital, commercial problem, the table needs no comments to show which filament types are best, that is, which ones are most economical to use. I have

Digitized by Google

put lowest in the table the cost of current per 16 candle-power of useful light from a standard 10 candle-power (mean horizontal) double coil filament lamp. This lamp gives 8.2 candle-power out from the tip. It is worth noting that a 10 candle-power lamp (so-called), with this type of filament, gives as much candle-power out from the tip as any one of the other types which are rated at 16 candle-power. Hence, such a lamp using only 35 watts gives as much useful light as any of the other four types which require 56 watts.

A NEW FORM OF FILAMENT

Since making the preceding tests, there have been developments which are worthy of special mention. A new type of filament for commercial lighting has come into being. The following matter describes its interesting features.

The Shelby filament, which is the most recent product of that company, has been designed and arranged especially to produce a high candle power in the vertical direction. In Fig. 12, is shown the average vertical distribution of candle-power from the new lamp. I call attention first to the arrangement of the diagram—I show the base of the lamp upward—exactly contrary to the conventional arrangement of vertical candle-power diagrams since 1885.

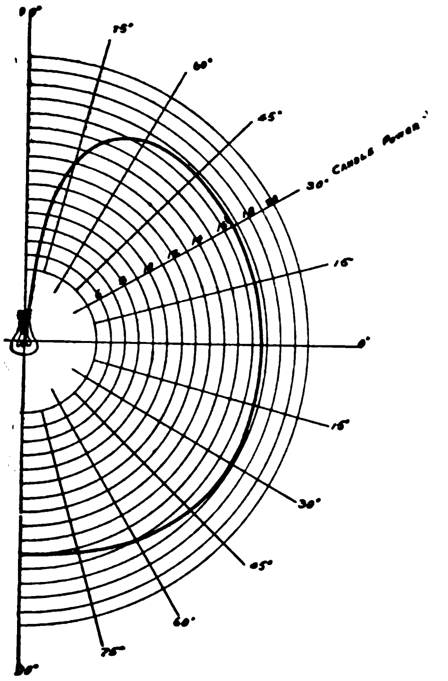

FIG. 12.

This method of plotting is natural and suggests at once the value of large candle-power downward (below the lamp). It is another step away from the conventions introduced into incandescent photometry long ago from gas photometer practice. I call attention next to the sort of filament and bulb tested—the rude sketch at the center of the diagram only suggests it. The filament itself is a good deal like the old Shelby coil (see Fig. 8 preceding), but with the circular coils flattened vertically, so that a much greater projected length of filament shows from the end. The bulb also is much flatter at the end than other standard forms, and the light comes through it nearly at right angles to the glass. The lamps, for which data is given, were made tipless. The loss of light through the tips of lamps having filaments so spreading as these would be very slight,

In the diagram there is to be noted a wonderfully maintained candle-power as one passes from the horizontal to the vertical direction.

The lamp as I received it was one of a lot, none of which were marked for voltage, and I set it at 16 candle-power when rotated in the usual way and made all subsequent measurements at the voltage so determined. The results set down are therefore on my rating—not on the manufacturers'. To understand the real meaning of the test data set down beside the curve of vertical distribution, comparisons must be made with similar values in the preceding part of this paper. The vertical candle-power (almost 15) is beyond comparison with that given by all filament forms except the double coil, which it even excels by 37 per cent. The mean spherical candle-power is also remarkable. The highest I know of in lamps rated in similar manner is below 14. A glance at the table of efficiencies of Fig. 10 shows by comparison with figures here the economy of the lamps. It may seem strange that a horizontal distribution is omitted in the test. This is purposely done. Regularity and irregularity of candle-power in horizontal direction is quite unimportant compared with the vertical. The average horizontal is shown in the vertical plot, and beyond this it is quite unnecessary to go, for all we need care to know of an incandescent lamp as regards its candle-power is—1st, what is the vertical candle-power and 2d, what ratio beteween this and the average horizontal.

A second test was made on a 10 candle-power lamp having the same form of bulb and filament. It was treated and rated in precisely similar ways as those used with the 16 candle-power lamps. A tabulation below shows the results procured. While the lamp had a lower efficiency than the 16 candle-power, it shows the same general characteristics. The vertical candle-power is 86 per cent. of the horizontal, and by the National Electric Light Association's rating, it would be of almost as high candle-power as if rated by usual manufacturers' rotating method:

10 CANDLE-POWER SHELBY FILAMENT.

Vertical candle power	8.7	(Watts per C. P.)	
Mean horizontal "	10.06		
Mean spherical "	97.8	on vertical C. P.	4.7
Mean with axis at 45 deg.	9.87	" horizontal "	4.05
Mean hemispherical	10.05	" spherical "	4.17
Cost of current per 16 C. P. useful light and per 500 hour service			$4.50

The above lamp used 41.8 watts at 112.35 volts.

I take it that the production of such a filament, such as vertical candle-powers and such efficiencies as these, are evidence of a demand for lamps of the sort. I cannot but feel that a new era in incandescent lighting has dawned when this is so. In future lamp specifications, we may look to see a requirement set down as regards the vertical candle-power of lamps, and the ratio of this to the mean horizontal. In fact it cannot be long before specifications for lamps for commercial lighting, will ask for a certain vertical candle-power and watts per candle-power on this rating, with a requirement as to a minimum horizontal intensity.

DISCUSSION.

Mr. W.C.L. Eglin, of the Edison Illuminating Company presented a reflector lamp, which he explained was made on the same lines as the Shelby lamp described in the paper, but with the effect magnified. The light from this lamp was wholly through the end, and he claimed for it an efficiency of 1.5 watts per C.P. in the direction the light was thrown. He further stated that the coil form of filament was old, having been used in some of Mr. Edison's early lamps. Mr. Eglin went on to say that the light out horizontally from an incandescent lamp, which strikes the walls, is important and necessary in producing good illumination, and so the horizontal candle-power should be considered. He attached no great value to initial measurements, and questioned the life and maintenance of candle-power of the Shelby coil filament.

Mr. Francis Head, of the Union Traction Company, in reply, stated that he had carried a number of such coiled filaments through a life test, and they had proved fully equal to any of the other makes.

Prof. Arthur J. Rowland, author of the paper, said that the paper carefully avoided the question of life and maintenance of candle-power, since the intention was to deal wholly with light distribution. The light distribution must remain the same throughout the life of any lamp, without respect to decrease in candle-power. He admitted that the coiled filament in the old type Shelby lamp was not new. and called special attention to the wonder that the advantages it gave had never been discovered; for this form alone gives a good candle-power distribution. He further said that the light out to the walls was of course a good thing, in order to have them properly illuminated; also, that the light reflected from them may be of a little use when the lamps in service give but low candle-power out from the end opposite the base. As a matter of fact, the useful illumination produced by light reflected from the walls is almost negligible since it has to pass through the long distance to the walls and back again. Its only value is to break up shadows and aid diffusion, as shown numerically in the paper. Moreover, if this kind of light is useful, the Shelby coil filament has as much light to send out to light walls and for reflection as any other, while the direct light from it is much greater. A reflector lamp has use in certain specific instances; for example, to supplement general lighting over a desk when it takes the place of a lamp with such a reflector as a McCreary shade. It is not practical for commercial lighting, however, since it limits the light absolutely to the direction in which the reflector sends it, and produces strong sharp shadows.

REFLECTOR LAMPS.

There is nothing new in reflector lamps; they were introduced into this country some years ago by a foreign manufacturer, and more recently have been produced by several American manufacturers, and classed with their special lamps Very recently the General Electric Company has brought out a reflector lamp of the same general style as those which preceded it.

For certain purposes, a reflector lamp is useful. It may supplement general illumination and give concentrated light to advantage where this is desired, but it cannot be successfully used for commercial lighting for several reasons.

The light is all directed one way, and absolutely cut off from every other direction. This gives one a bright spot of light under the lamps, but dark spaces between, around, and above them—quite dark except for reflection from the few objects illuminated. Nothing can be more trying to the eyes than to look from brightly lighted objects to those not lighted at all, and back again.

An ordinary reflector lamp, acknowledged to consume 50 watts, is extravagantly used for lighting even though the efficiency may be 1.5 watts per C.P. in the direction in which the

Digitized by Google

light is thrown, for the reason that it illuminates only a small area. With it, general illumination would be necessary at additional cost.

A reflector lamp combines a reflector and a lamp in one. While the combination may cost less than lamp and reflector bought separately, when the filament burns out the reflector is gone too; hence, at the price these lamps are offered, they are too expensive for general use. Separate reflectors are much to be preferred where it is really necessary to use them.

In comparison with the other lamps which are used regularly in commercial lighting, the reflector lamp suffers. It gives no horizontal light at all, and the importance of a certain amount of this light is recognized by all good lighting engineers. Any lamp which gives enough light in the vertical direction to be economical and gives light out besides, in the directions which assist general lighting and diffusion, is far superior to a reflector lamp. It is found that the old double coil filament has these features, but it is greatly exceeded by the new Shelby coil (about to be placed on the market), as is shown by photometric tests. Whether a lamp which gives 16-candle power horizontal and 16-candle power vertical is better than one which gives 6-candle power horizontal and 16-candle power vertical, is an open question. Everyone must agree that there is some limit below which the horizontal candle power of a lamp should not be decreased, and this is before the zero point is reached.

If reflectors over lights to throw the whole light flux in the vertical direction are necessary for any sort of lighting, that lamp is best which uses a form of filament giving high candle power in the vertical direction without the reflector. By reflection, one adds only to the direct light. Of two lamps having a given light flux to reflect, that one having most initial candle power in the direct rays, will have the brightest light after a reflector is put in place. A Shelby coil filament turns out then to be better than any other form when used with a reflector or shade as well as without.

PARIS LETTER.

Special Correspondence of ELECTRICITY.

Direct Current Generators at the Paris Exposition.

In a previous report we gave the list of the various generators supplying motive power for the electric lighting of the Exposition, we will now examine each of these generating groups separately, commencing with those of the direct current generators.

GROUP 1—SOCIETE ALSACIENNE DES CONSTRUCTIONS MECANIQUES DE BELFORT.

The group consists of a vertical two-cylinder double-expansion-condensing Woolf engine with Corliss valves. Its effective power at an initial pressure of 8 kilos per square centimeter amounts to 1,200 hp. at an angular speed of 70 revolutions per minute. The diameter of the high-pressure cylinder is 0.85 meters, that of the low-pressure cylinder is 1.35 meters. The piston stroke is 1.20 meters. The driving shaft with two cranks set at 180 degrees has a total length of 9 meters and weighs 10 tons. It carries on one end a fly-wheel of 5.7 meters diameter weighing 31 tons, and on the other the armature of the dynamo. This driving-shaft is supported on six bearings.

The full capacity of the dynamo is 1,500 amperes at 500 volts. The 12 induction poles are cores of cast-steel, 45 centimeters long and presenting a section of 2,100 square centimeters. The coils are of copper wire of 21 mm. thick. The total resistance of these coils, arranged in series, is 24 ohms. The whole of the inductor is solidly supported on one side of the steam-engine base. This arrangement of the pole-pieces admits of very short magnetic circuits and a very powerful magnetic flux on account of the large space (section) given to the cores. The dynamo is wound in multiple arc. The armature consists of a gramme-ring of large size with a smooth core having an exterior dimeter of 3.81 meters, interior diameter of 3.42 meters. The disks of the annualar core are of special soft steel-plates, insulated by gum-lac paper. The whole armature is kept in position by a cast-iron star of 39 arms which is keyed to the driving-shaft. The diameter of this star is 4 meters and weighs 7½ tons, being cast all in one piece. The winding is on U-shaped copper plates set in paper sheaths and placed in horseshoe form towards each other on the internal surface of the core, so that all the disengaged ends extend above the exterior surface. Each winding turn has a section of 60 square millimeters. The total resistance of the armature at a temperature of 40 degrees Celsius is 0.006 ohm; the number of turns is 2,268 and the tangential speed 14 m. per second. The current is collected by 12 sets of brushes, four of them to each set; the diameter of the brush-support is 4½ meters.

The loss in the dynamo is 22.5 kilowatts working at full capacity, with an excitation of 9,000 watts. Joule's effect in the armature is 13,500 watts, hysteresis and Foucault's currents 7,800 watts. The electrical efficiency is therefore 97 per cent.

GROUP 2—SOCIETE DECAUVILLE AINE AND CREPELLE AND GARAND.

The horizontal compound steam engine is 1,200 hp. with the cylinder diameters of 0.71 and 1.32 meters respectively and a stroke of 1.60 m. This engine drives a shaft carrying the armatures of two dynamos of equal size. Each of them have an output of 400 kilowatts at an angular speed of 75 revolutions per minute, they can furnish 1,600 amperes at 250 volts. The two parallel-coupled dynamos furnish 3,200 amperes at 250 volts. This consequent-pole inductive construction carries 10 cast steel plates of 340 millimeters long serving as a core to the induction coils which are wound with nine layers of copper wire of 5.3 millimeters diameter.

The armature has a cast-iron core formed of two pieces and keyed to the driving shaft; it serves as a support for the armature core formed of rings of assembled plates 0.5 millimeter thick and insulated by lac-paper. The winding is of the multipolar thick drum type with jointed sections in parallel. It contains 625 rectangular profile cable sections of two, six, four by seven millimeters, insulated by four layers of cotton. The connections are made by double copper plates 30 centimeters long, three centimeters wide and 1.8 millimeters thick. The length of the collector is 2 m. with a width of 26 cm. It carries 625 copper plates insulated by mica. The current is taken off by ten series of carbon brushes. The total weight of the two dynamos is 58 tons, each armature weighing 12.5 tons.

GROUP 3—BREGUET AND SOCIETE DE LAVAL.

The two groups three and three[a] are the same. Each of them consists of a Laval steam-turbine of 300 hp. directly coupled to two twin dynamos in series.

Each of these dynamos is capable of developing 100 kilowatts at an angular speed of 780 revolutions per minute and to yield under normal condition 825 amperes at 125 volts. The field pieces are case-hardened composed of four poles, two of them only are furnished with energizing coils. The poles measure 410 by 284 millimeters giving an area of 1,164 square centimeters. The diameter of the bore is 568 millimeters, that of the inter-air-space seven millimeters. Each coil is made up of two copper wire sections. The energizing current strength is 1.6 amperes per square millimeter, and the number of ampere turns for each field is 15,000. The dynamo is energized in multiple arc. The rheostat is fitted up with twenty contacts and has two handles, one is used to change the resistance ohm by ohm, while the other is intended to obtain intermediate resistances. The armature has a laminated and toothed ring-core. The exterior diameter is 554 millimeters, the interior diameter is 310 millimeters. It is mounted on a cast-iron star furnished with six arms. The two armatures are keyed directly to the two turbine driving shafts. The core contains sixty half closed notches. The winding is of the drum type. The current density in the armature is 2.69 amperes per square millimeter. The armatures of the two dynamos can be coupled either in series or in parallel.

The collector carries 120 plates; its diameter is 270 millimeters. The current is collected by four series of brushes arranged in couples. The output at full load is 825 amperes, each brush carrying from 34 to 35 amperes. These two groups of direct current generators are intended to balance the bridges of the three wire general distribution at the Exposition. As the two dynamos in each group can be coupled in series, a potential difference of 250 volts between the neutral and the two other wires can be provided for.

The Laval 300 hp. turbines have driving wheels of 80 cm. diameter and a speed of 9,000 revolutions per minute. The shaft of this wheel is turned by means of a pinion on two toothed wheels revolving at 780 tons per minute. These wheels operate through elastic couplings, and they carry the armatures in the same direction. Steam is supplied to them at a pressure of 10 kilos per square centimeter, and distributed by eight valves, four of these valves are conically shaped for conducting the exhaust to the condenser, and two are of cylindrical form for the free exhaust, while two conic spring valves are balanced for pressure at 7 kilos per square centimeter. The consumption of steam per effective hp. hour is 16 kilos with free escape and 7.5 kilos with condensation.

The installation of the whole group, including the turbine, the speed-reducing apparatus and the two dynamos required a space of 4,116 meters long by 1.91 meters wide and 2.38 high, the total weight of the complete outfit being 11,500 kilos.

A GERMAN paper states that it is proposed to use the great beds of peat which exist in Northern Germany for the purpose of producing electricity on a large scale. There are about 1,000 square miles of peat area, and an enormous quantity of good fuel could be obtained therefrom. The fuel from this source should prove to be very cheap when compared with coal, and both producers and consumers would, in all probability, obtain some benefit from its use.

THE CONVENTION OF MUNICIPAL ELECTRICIANS.

The fifth annual meeting of the International Association of Municipal Electricians was held in Pittsburg, September 25, 26 and 27, and proved one of the most successful gatherings this Association has yet held.

The first session was called to order Tuesday morning by President William Brophy, of Boston, Mass. The Rev. John A. Jayne, of Allegheny opened the session with a prayer, after which S. U. Trent welcomed the electricians to the city of Pittsburg. The response on behalf of the Association was made by President Brophy, who commended Mr. Mead, the committee of arrangements, and the city, on the enterprise and hospitality showed in the arrangements made.

The President then delivered his annual address, after which reports from the various committees were read.

During the convention the following papers were read and discussed: "Benefits to Be Derived From Our Association," Captain William Brophy, Boston, Mass.; "Contact Points," Frank C. Mason, Brooklyn, N. Y.; "Trials and Troubles of Instituting and Enforcing Municipal Inspection and Control," M. G. Canfield, Grand Rapids, Mich. A paper on "Automatic Fire Alarm Systems" was read by Charles Bergher, of Boston, as was one entitled the "Advantages and Disadvantages of High and Low Potential Conductors on the Same Poles," by F. W. Jones.

During the meeting Morris W. Mead referred to the subject of emergency work, and asked the members to induce their municipalities to adopt fire and police alarms which would work instantly all over the city at any time of the entire day.

There were about 250 persons in attendance including quite a number of ladies. The social features of the convention were most successful and were carried out as originally intended.

The next meeting of the Association will take place at Niagara Falls, N. Y.

Trade Publications Received.

We are in receipt of a handsomely gotten up pamphlet containing some fifty odd pages, descriptive of and illustrative of the calculagraph, which is coming more and more into use in telephone exchanges. By means of this instrument, which is manufactured by the Calculagraph Company of 9 Maiden Lane, New York, the time which elapses during a toll conversation is mechanically recorded.

An interesting catalogue has reached this office descriptive of the Long Automatic Lamp Support by means of which any chance of a carbon trimmer being shocked while handling a lamp, is done away with. These supports are manufactured by Harry Long, Greentown, Ind.

The American Endoscopic Company of Providence, R. I., has sent us a booklet which illustrates and describes in detail the many types of miniature lamps manufactured by this well-known concern.

The Kellogg Switchboard & Supply Company, Chicago, has recently gotten out Bulletin No. 1, which describes in detail the many varieties of telephones turned out by the company. The various fixtures and apparatus are illustrated by means of handsome half tones, while the many advantages of this type of 'phone are clearly set forth in plain, readable type.

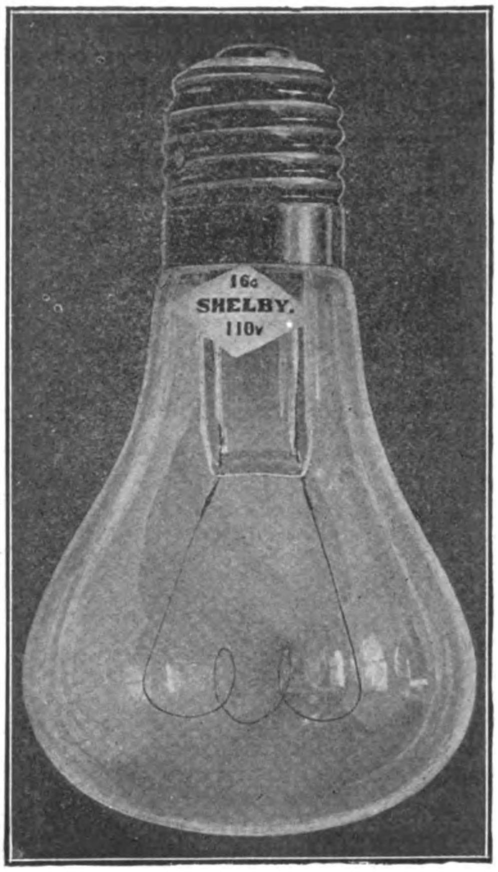
LEGAL NOTES.

Judge Traux has granted an order dissolving the firm of Schmidt & Bruckner, an electric company of 135 Elm street, New York City, and appointed Lambert Schmidt permanent receiver. Mr. Schmidt was appointed temporary receiver on January 5 in a suit brought by Frederick C. Bruckner against Lambert Schmidt for a dissolution of the copartnership on account of a disagreement between them.

The litigation over the Richmond, Ky., electric plant, which has been going on for more than a year, seems to be at an end. In the Circuit Court Judge Scott gave a judgment for $5,900 against the company, which is composed of D. J. Hauss, of Cincinnati; F. H. Adair, of Carlisle, and others. The contract between the plaintiffs and defendants, by which the former gained an interest in the plant, was rescinded and the plant ordered sold. The plaintiffs allege that fraud was practised by the defendants.

The New Shelby Lamp.

On page 198 of this issue will be found an article entitled "Mistakes in the Rating of Incandescent Lamps." The lamp shown in the accompanying illustration is the one that Mr.



Arthur J. Rowland tested so satisfactorily. This lamp is manufactured by the Shelby Electric Company of Shelby, Ohio,

PERSONAL MENTION.

Mr. Edward Adams of Toledo, O., has been appointed general manager of the Sandusky, Milan & Norwalk Electric Railroad.

Mr. Ernest J. Berg of the General Electric Company o Schenectady, N. Y., went to Europe recently and expects to be abroad about four months.

Mr. Charles T. Ames, formerly of the Boston & Maine Railroad, has been appointed general freight agent of the Stillwater & Mechanicsville, N. Y., Street Railway Company and the Greenwich & Schuylerville Electric Railroad.

Mr. Clarence Leach of Gouverneur, N. Y., has resigned his position as head electrician of the Oswegatchie Light & Power Company to accept a similar position with the Electric Light Company of Potsdam, N. Y.

INCORPORATIONS.

The New York, Philadelphia & Norfolk Telegraph Company, Wilmington, Del. Capital stock, $150,000.

The Lake City Electric Company, Lake City, Ia. Capital stock, $20,000. Incorporators: J. J. Coady, J. B. Smith, Ira R. Amey, Alva Conskaddon and M. E. Hutchison.

The Consumers' Heat & Electric Company, Bloomington, Ill.—to furnish steam and electricity for all purposes. Incorporators: George P. Davis, Edward Thorp and George S. Hanna.

The Gowanda Electric Light & Power Company, Gowanda, N. Y. Capital stock, $10,000. Directors: Charles E. Sipple, Charles P. Dean and George B. Pratt, all of Gowanda.

The Merchants' Gas & Electric Company, San Francisco, Cal.—to make and deal in gas and electrical appliances, etc. Capital stock, $1,000,000. Directors: V. Stow, R. J. Woods, A. A. Sanderson, E. C. Hutchinson, San Francisco, and E. B. Davis, Oakland.

ELECTRICAL PATENT RECORD.

[This department is edited by OSCAR A. MICHEL, Solicitor and Attorney for AMERICAN AND FOREIGN PATENTS, at 302 and 304 Broadway (Room 1204), New York City, also at 639 F street, N. W., Washington, D. C., who has been identified with this work before the U. S. Patent Office for more than fifteen years. Any inquiries upon the above subject as well as printed publications containing all information regarding the cost of United States and Foreign Patents, Trade Marks, Designs, etc., will be given free upon application by addressing OSCAR A. MICHEL, Nos. 302-304 Broadway, New York City, N. Y., or 639 F street, N. W., Washington, D. C. Copies of any patent published can be furnished upon payment of ten cents. When ordering give name, date and title of invention wanted.]

LETTERS PATENT ISSUED SEPTEMBER 25, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

658,336. Electric Railway. Edward M. Bentley, New York City. Filed Aug. 5, 1896.

658,445. Electric Car. Arnold A. Ingraham, Lowell, Mass. Filed Oct. 2, 1899.

658,541. Bond-Tie for Electric Railways. William A. Downing and James T. McHugh, Pittsburg, Pa. Filed Feb. 21, 1900.

658,581. Trolley. Alphonse Piton, St. Sauveur de Quebec, Canada. Filed April 17, 1900.

658,702. Car-Fender. John L. Conner, Washington, D. C. Filed May 16, 1900.

658,745. Trolley-Wheel. David F. L. Jones, Columbus, Ga. Filed Aug. 12, 1899.

ELECTRIC LIGHTS AND APPLIANCES.

658,423. Carbon Rod for Electric-Arc Lamps. Hugo Bremer, Neheim, Germany. Filed Aug. 5, 1899.

ELECTRICAL MACHINERY AND APPARATUS.

658,741. Electric Welding-Machine. Otto Parpart, Cleveland, Ohio, assignor by mesne assignments, to the Standard Welding Company, same place. Filed Jan. 31, 1898

MISCELLANEOUS.

658,388. Mechanism for Imparting Successive or Alternating Movements. Elisha Moore, Meductic, Canada. Filed Nov. 15, 1899.

658,431. Dynamo-Brush. Carl Endruweit, Berlin, Germany Filed Aug. 7, 1899.

658,476. Dynamo Regulation. Imile E. Storey, Trenton, N. J. Filed Feb. 23, 1900.

658,483. Process of Oxidizing Negative Electrodes for Primary Batteries. Clyde J. Coleman, Chicago, Ill. assignor to Thomas J. Ryan, New York City. Filed Dec. 20, 1899.

658,601. Appliance for Imparting Heat and Electricity to the Body. Ignaz Timar, Berlin, Germany. Filed Nov. 10, 1899.

658,612. Telephone-Directory. William J. Bell, Baraboo, Wis., assignor of one-half to Herman Grotophorst, same place. Filed May 24, 1900.

658,664. Thermostat. William E. Mack, Oswego, N. Y. Filed Sept. 19, 1899.

658,698. Electric Furnace. Charles S. Bradley, New York City, assignor to the Cyanide Company, Ampere N. J. Filed Feb. 10, 1900.

658,706. Electric Stove. Herbert S. Dowsing, London, Eng. Filed Sept. 12, 1899.

658,733—658,734. Secondary Battery. Clyde J. Coleman, Chicago Ill., assignor, by mesne assignments, to the General Electric Storage Battery Company of New Jersey. Filed Dec. 8, 1899 and Oct. 2, 1899.

658,739. Coin-Setting Electric Meter. Frank Kramer, Chicago, Ill. Filed Nov. 6, 1899.

REISSUE.

11,857. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed Aug. 18, 1900. Original No. 652,457, dated June 26, 1900.

Digitized by Google

THE TELEPHONE WORLD.

Death of John E. Hudson.

John E. Hudson, president of the American Bell Telephone Company, dropped dead from heart disease on the morning of October 1, in the waiting-room of the Beverly station of the Boston & Maine Railroad in Boston.

Mr. Hudson was born in Lynn, Mass., on April 3, 1839, and had been connected with the Bell Telephone Company since 1880, when he became counsel for the company. In 1885 he succeeded T. M. Vail as general manager, and four years later he was elected to the presidency, succeeding Howard Stockton. Mr. Hudson was a graduate of Harvard, class of '62.

The stockholders of the Tidewater Telephone Company met in Gloucester, Va., a short time ago. J. A. Galliger, representing the Old Dominion Steamship Company, was elected chairman, and L. C. Catlett, secretary, of the meeting. W. E. Corr was unanimously elected president and W. A. Withers was elected vice president; Messrs. J. W. Down and W. N. Trader, of Mathews; J. A. Bristow, of Middlesex, and Messrs. J.L. Taliferro, and R. B. Weaver, of Gloucester Courthouse, were elected directors. All of these except Mr. Weaver were members of the former board. The superintendent's report showed that the company now has 175 miles of pole line, and 428 miles of wire, and 107 stations in operation. Arrangements were made to open an exchange at Saluda, and to extend the lines to Tappahannock, Va., as quickly as possible.

Millbury, Mass., patrons of the telephone are trying to study out wherein they would be benefited by the proposed central office and reduced rates for local service offered by the New England Company. If it is offered to put in telephones for local service at $18 a year and then charge 10 cents for every message sent out of town it is hard for subscribers to see the advantages of the new proposition. There is hardly a patron of a telephone in town who does not talk out of town at least four times a day. At the 10-cent rate this would amount to a good deal more than $100 per year. When the $18 for the local telephone is added it is safe to say that the price of the $18 local telephone will amount to about $150 a year. Under the proposed arrangement, a patron wishing to get a man who has the unlimited service and not the local will be under the necessity of paying a toll of 10 cents.

The special telephone committee appointed by the Board of Trade and Business Men's Association to investigate the question of rates in Norfolk, Va., recently made up a report to be forwarded to the board of directors of the association. No information was given out concerning the meeting, except that the committee's report had been made up. This committee has met several times and officers of both the Southern States and Bell Telephone Companies have appeared before it. At present it is almost impossible to forecast the committee's action. The report will be mild in terms, but adverse to the Bell Telephone Company.

The Minnesota Central Telephone Company held a meeting recently in St. Paul. The company operates about 800 miles of telephone line in the central part of the State. The directors chosen were: D. N. Tallman, John Williams, Willmar; Charles Webster, A. Webster, Waucoma, Ia.; E. G. Porter, Owatonna, Minn. The officers elected are: D. N. Tallman, president and treasurer; Charles Webster, vice-president, and John Williams, secretary.

The new telephone line from Chili to Churchville, N. Y. which was commenced two months ago is nearly completed and will be opened in a few days. The company has experienced no little trouble in getting the line through the village and has had to meet the objections of many of the village people who protested against the trimming of shade trees along the highway. The company will extend the line to Buffalo.

The Citizens' Telephone Company, a part of the system of the United States Telephone Company, is expending $125,000 in Fostoria, O., in the entire rebuilding of the local telephone plant. It has put in 21,000 feet of cable; every telephone in use will be a long distance 'phone, and a six hundred drop switchboard is being put in the new suite of offices.

Wabash, Ind., now has telephone communication with Indianapolis by the new independent line, running by way of Marion, Kokomo, Tipton and Noblesville, Ind. The rate is 40 cents for five minutes, as against 55 cents for three minutes with the Bell Company.

Long distance telephones to connect Fayetteville, Hamlet, Sanford, Red Springs and other towns in that section of North Carolina will soon be erected. The incorporators are Dr. H. W. Lilly, Dr. Thomas M. Rose and Mr. W. F. Leak.

Two Uses for One Wire Practiced in Berlin.

Consul-General Guenther, of Frankfort, gives some interesting facts about the plan adopted in connection with the Berlin fire brigade service of telegraphing and telephoning simultaneously over one line. He says:

"There are fifteen brigade stations in Berlin, each of which is served by a special network of fire alarms. From these stations underground wires radiate in all directions, each wire being connected with a great number of alarm pillars. The alarms are arranged for automatic working, and to each is fitted a key for telegraphing to the station. As it is, however, a very great advantage to be able to maintain during the progress of the fire a good connection between the alarm pillars nearest the fire and the brigade station, exhaustive trials have been made with a specially adapted telephone, which have resulted in the general introduction of the same.

"To the Morse apparatus at the station a stand is attached from which a micro-telephone fitted with a battery switch and a second receiver are suspended. The remaining apparatus is inclosed in a flat box and placed under the table. This box contains an induction coil, a condenser, and a circuit key. As it would be expensive to equip each of the fire, alarm posts with telephone apparatus, a portable set is used, which may be attached to the posts by means of a plug and socket provided for the purpose. Such a portable set is carried by each of the brigade carts, there being some eighty now in use. The brigades' cycles are also equipped with sets which are very compact in design.

"Experience with the system has shown that the switching in of the telephone apparatus in no way influences the telegraph service. During simultaneous telegraphing and telephoning a slight knocking is perceptible in the telephone, which, however, does not destroy the audibility."

That the business men and corporations of Buffalo, says a daily of that city, are at last awakening to the fact that the telephone service is about as bad as it can possibly be, and the charges for service inconsistently exorbitant, is shown by the action of the Buffalo Creek Railroad officials in their refusal to continue the use of the telephone in the trainmaster's office. General Agent E. F. Knibloe was interviewed on the subject recently in response to a question as to whether the abominable service was responsible for the company's action, he said: "It is not true that we are dispensing with Bell telephones on account of poor service. Although there have been many grounds of complaint on this account, that has not been the determining cause. The reason is that we consider it an extremely exorbitant rate. We were paying $180 a year for unlimited service on a single circuit with one instrument. At the expiration of the term on September 1st the telephone company canceled this contract and notified us of a new rate, which, upon the basis of last year's business of a little over 12,000 messages, would cost us a little more than $380."

The New England Telephone Company has announced that it will furnish telephones free to the residences of business men of Worcester, Mass., who have telephones at their offices for which they pay. The service will be on a six-party line and the offer is conditional in one respect. All residences to get the 'phones free must be near some existing line. No new line will be laid for the free service. 'Phones can be used free in residences until February 1, or a little over four months. After that the regular rate will be charged or the telephone taken out. The reduction there is also undoubtedly caused in part by the fact that the New England wants to jump in ahead of the independent company.

The work of constructing the Cortland, N. Y., Home Telephone Company's lines is progressing rapidly. The new company has already drawn over one hundred contracts for telephones, and has one hundred applications on hand for which contracts have not yet been made.

The Western Minnesota Telephone Company has issued bonds to the amount of $26,000, for the purpose of building a line to Glencoe, and for improving the lines and circuits between Glencoe and Granite Falls, Minn. The stockholders met in Minneapolis recently and decided upon the improvement. The company will have close connections with the Bell Company in the Twin Cities.

The People's Telephone Company, whose headquarters are at Knoxville, Tenn., is preparing to build a line to Williamsburg, Whitley County, Ky., and to other points in that section. This company may also put in an exchange at Williamsburg.

The New York & New Jersey Telephone Company, of Passaic, N. J., is now installed in its new building, at 143 Prospect street. The change of the central office from the old location to the new building was effected without any delay or inconvenience to the system, and the subscriber were not bothered in the least.

Free Telephone Proves a Success.

The experiment of educating the people up to the use of the telephone by giving them the use of an instrument free of expense for several months has proved a success in Augusta, Me. Now the number of telephone users in that city is greatly increased.

Several months ago the telephone company arrived at the conclusion that there was not enough telephones used in the city, and the only reason why more people were not using the convenience was that they did not appreciate its value. Accordingly it was determined to give everyone who wished the benefit of a free trial service. The linemen were busy for a long time putting in instruments with the result that miles of new wire were strung in the city.

In fact so many instruments were put in that it was necessary to do away with the custom which had been so long in vogue, that of calling for a subscriber by name. A new rule was made so that it is now necessary to call by numbers. With the innovation of the new rule the people soon began to see that by adhering strictly to the rules of the company they could get connection much quicker than under the old system. The result is that Augusta now has an enviable telephone system.

Of all those who had the instruments put in on trial but 16 have had them taken out after the free trial service. The scheme of educating the public to the new system has proven so successful that the same idea will be tried in other cities in that State. It is understood, therefore, that in a comparatively short time nearly every city in Maine will be given the privilege of trying the new free system for a time.

The new telephone line between Northwood and Northwood Narrows, N. H., was completed recently, connecting the trunk line of the New England Telephone Company from Exeter to Concord, N. H. Lines were in operation before from Exeter to Northwood and from the Narrows to Concord, and the line, besides connecting the two sections in one direct line, furnishes telephone service for the villages of Northwood Ridge and Northwood Center, which lie between.

The Progress Telephone & Telegraph Company of West Milton, O., has made application to the city authorities of Cincinnati for a franchise to construct and maintain a toll station in that city. The same was referred to the board of city affairs.

At a meeting at Columbia, Tenn., of the directors of the Citizens' Telephone Company, it was decided to combine the offices of president, secretary and treasurer, and the president, Dr. A. J. Porter, was elected to fill the position.

The village council of Two Harbors, Minn., has granted a fifty-year telephone franchise to Thomas Owens and his assigns. This is for the new system being built by the Duluth & Iron Range Railway.

A new telephone line has lately been established between West Liberty and Caney, Ky., a distance of ten miles. This line connects with the Morehead and West Liberty telephone line.

The Cumberland, Tenn., Telephone Company is extending a line from Jackson to connect Carroll, Medina and Humboldt. The line will prove a great convenience.

The Weed Abbey Telephone system is to be extended to Jericho, Vt., and it will connect at that point with the New England Telegraph & Telephone Company's lines.

Telephone connection has been made between New Market and Luray, Va. This connection gives Luray use of the entire Valley.

Weymouth, Mass., is to have a telephone exchange.

TELEPHONE INCORPORATIONS.

The Noble County Telephone Company, Albion, Ind., Capital stock, $15,000. T. A. Huston is the president of the board.

The Shiloh Mutual Telephone Company, Huntsville, Ill. Capital stock, $900. Incorporators: E. H. Grosclaude, J. E. Croxton and T. A. Wilson.

The Wayne & Pike Independent Telephone Company—to build a line in Pike, Wayne, Monroe and other counties in Pennsylvania. Capital stock, $6,000.

The Buchanan County Telephone & Telegraph Company, Independence, Ia.

The South Whitley Telephone Company, South Whitley, Ind. Capital stock, $3,000.

The Mineral City Home Telephone Company, Minera City, O. Capital stock, $12,000. Incorporators: G. J. Markley, T. E. Wilson, E. Vankirk, J. J. Kennedy and C. D. Juvinall.

GENERAL NEWS.

What is Going On in the Electrical World.

LIGHTING.

Almonte, Ont.—A special election will be held October 20 to vote on the question of issuing $3,000 in bonds for erecting a municipal light plant.

Arcadia, Ind.—The harness factory and electric light plant here, owned by A. E. Goodykoontz were totally destroyed by a recent fire causing a loss of $15,000.

Atlanta, Ga.—The Atlanta Railway & Power Company, of which J. B. Burt is president, has been granted a franchise for the construction of an electric light plant.

Carlyle, Ill.—The city council will soon close the contract for an electric light plant for this city.

Carthage, N. Y.—The American Electric Light Company has leased water power of Dr. F. E. Robinson, and is now engaged in attaching a fifty-light arc dynamo to the wheels. This additional power will operate the arc lights, leaving the present power at the station for running the incandescents.

Chicago, Ill.—Dr. T. W. Goodspeed, secretary of the board of trustees of the University of Chicago says the new building for the University Press and Power & Lighting Plant will cost $250,000, and although the money has not yet been received for its construction, Dr. Harper is confident it will be erected next year.

Clinton, S. C.—Arrangements are being made and work will soon commence for the erection of an electric light plant. C. S. Moody can be addressed.

Florence, Ala.—E. J. O'Beirne, of Birmingham, has petitioned the city council for a franchise to build an electric light plant.

Flushing, N. Y.—Electric light trunk wires from this place will be extended to Elmhurst, and thence through Winfield and Woodside to Grand Street Ferry, Brooklyn.

Groton, Conn.—It is predicted by a business man here that it will not be many months before that part of Groton comprised in the Groton Fire District will be equipped with an electric lighting plant.

Henrietta, Tex.—The Henrietta Gin & Light Company, incorporated with $5,000 capital stock, contemplates the erection of an electric light plant.

Hickory, N. C.—The establishment of an electric light plant, or the granting of a franchise for such a plant, is talked of here.

Hutchinson, Minn.—This city will have electric lights in the near future. A company has been formed with a capital of $25,000.

Lake City, Fla.—A stock company is being organized to build an electric lighting plant here for the purpose of lighting the city.

Lake Providence, La.—This city is now asking bids on its authorized $17,500 of bonds for construction of an electric light plant, etc. Address G. M. Franklin, mayor.

Lancaster, Ky.—The electric plant and flouring mill have reduced operations on account of the scarcity of water.

Manchester, Ia.—At a special election the people of this city voted to grant a franchise for an electric light plant.

Manchester, Va.—The light committee will soon ask for bids for lighting the city. A. H. Meyer, chairman of committee.

Middleport, N. Y.—The question of municipal ownership of an electric light plant will be voted on by Middleport tax payers.

Minot, N. D.—The question of electric lights for this city is once more being agitated.

Mt. Morris, Ill.—The village authorities have received two applications for the privilege of putting in an electric light plant. C. H. Whitman and Ed. Thomas are the petitioners.

New York City.—The freight steamer L. Boyer, which plies between Flushing and this city, has been equipped with an electric light plant.

Norwalk, O.—An election will soon be called to vote on the proposition to issue $9,000 in bonds for the establishment of a municipal incandescent light plant.

Pen Argyl, Pa.—Owing to a water famine here the electric light plant was lately closed down.

Pine Bluff, Ark.—It is reported that W. H. Keyser and J. B. Bradley of Chicago, have lately been here in the interest of the proposed electric light plant.

Plymouth, Wis.—The common council lately accepted the bid of W. H. Wheeler of Chicago for putting in a system of electric lights and waterworks.

Richwood, O.—The electric light plant owned by Edward Schambo burned to the ground recently, entailing a loss of about $17,000.

Riverside, Cal.—The trustees have accepted the plans for the proposed electric light plant, and will receive bids for its erection until October 10.

South Elgin, Ill.—An electric light plant is to be establish in the Panton mill at this place for lighting the hotel, etc.

Story City, Ia.—This town is being canvassed for putting in electric lights, and it is claimed that the prospects are good.

Union Point, Ga.—The Union Manufacturing Company of this place wants bids on a 200-light 20 candle power dynamo.

Willimantic, Conn.—A recent resolution introduced by Alderman Taylor authorizing the construction of a municipal gas or electrical lighting plant was passed.

Windsor, Mo.—J. W. Carver has been awarded a contract to put in an electric light plant at this place.

STREET RAILWAYS.

Akron, O.—Hon. V. A. Taylor of Bedford lately appeared before the board of county commissioners and asked for a franchise for the proposed Bedford-Ravenna electric railway through Summit County.

Albion, Mich.—The city council at a recent meeting granted a 30-year franchise to the Kalamazoo Valley Electric Railway Company, represented by F. N. Rowley, of Kalamazoo.

Buffalo, N. Y.—Eastern capitalists have been interested in a company organized to build another electric road between this city and Rochester, provided the State Railroad Commission will permit.

Claremont, N. H.—Parties were recently here investigating the merits of the proposed electric railway.

Cleveland, O.—The Cleveland, Elyria & Western Electric Railway will extend its line to Medina, branching out at Berea.

Columbus, O.—D. L. Worthington and F. Johnson of the recently incorporated Columbus, Mt. Sterling & Columbus Electric Railway Company, are perfecting arrangements for their road to enter Franklin County and this city.

Concord, N. H.—The Boston & Maine Railroad has filed a petition with the State Supreme Court asking for authority to build an electric railroad from this city to Nashua.

Croswell, Mich.—The council has granted a franchise to the Detroit, Lake Huron & Lexington Railway Company to operate an electric railway within the village limits.

Emmett, Mich.—At a recent meeting of the common council a resolution was passed granting a franchise through this village to G. Lovejoy and others for an electric railway.

Exeter, N. H.—W. D. Lovell will apply at the next session of the Legislature for a charter for an electric railway between this place and New Market to be known as the Exeter & New Market Street Railway.

Florence, Col.—The permanent survey for the line of the Florence Electric Street Railway Company will be commenced within the next three weeks. H. A. Cook, J. Reed, H. Robinson, J. B. Meserve and A. B. McFall are interested.

Freehold, N. J.—There is a rumor that a company is forming for the purpose of building a trolley line from this place to the shore.

New Orleans, La.—The power house of the City Railway Company is in ruins. Major Baer, manager and receiver of said company, will have the system put in order at once.

New York City.—There is every likelihood now that a through trolley road from this city to New Haven will be built.

Penn Yan, N.Y.—The survey for the extension of the Penn Yan, Keuka Park & Branchport Electric Railway from Branchport to the Pulteney landing on Keuka Lake has been completed. The extension will cost $50,000.

Phoenixville, Pa.—A trolley line connecting Bridgeport and this place, passing through Valley Forge, will soon be started on the west bank of the Schuylkill.

Pine Bluff, Ark.—W. H. Keyser, a Chicago street railway promoter, intends operating an electric street railway here.

Sylvania, O.—Engineers have recently been at work surveying an electric railway route to this place.

Wapakoneta, O.—The council recently granted the final franchise to F. D. Carpenter, L. Coe and J. M. Mayor, capitalists of Cleveland, to construct and operate an electric street railway through this village.

MANUFACTURING.

Chicago, Ill.—Carlos S. Andrews, Eugene G. Fassett and Guy Brockway are interested in a concern recently formed here, known as the Station Equipment Company, which will manufacture electrical and mechanical machinery with a capital of $25,000.

Cincinnati, O.—The Motor Machine Company was organized here a short time ago by M. R. Conway, M. H. Wilson, T. M. Woods, Peter Renner and H. L. Gordon for the purpose of manufacturing engines, motors and all kinds of machinery.

Pittsburg, Pa.—The National Cable & Wire Company of this city, with a capital of $1,000,000, purchased the mower and reaper works in Latrobe, and is making preparations for an early start to manufacture electrical supplies.—The Shadowless Arc Light Company was recently formed here to manufacture and deal in shadowless arc lights, etc., on a capital of $15,000. W. C. Nixon of Pittsburg, J. J. Houlahan, C. Tepel and C. Koenig, all of Bennett, have an interest in the concern.

Portland, Me.—The Pawtucket Brass Foundry Company was recently organized here for the purpose of manufacturing and dealing in electric railroad supplies with brass and metal foundings with $50,000 capital stock. The officers are: President, Winfield S. Carpenter of Salem, Mass.; treasurer, James W. Sully, of Hyde Park.

San Francisco, Cal.—The Electrolysis-Proof Conduit Manufacturing Company was lately formed here with a capital of $200,000.

Washington, D. C.—F. C. Behrens, L. C. Brooks, C. C. Wheelan, C. H. Neely and R. W. Neely, all of this city, are interested in the Neely Electric Company, formed to manufacture, sell and deal in articles, appliances, etc., in the electrical line with a capital of $50,000.

COMPANY MATTERS.

Columbus, O.—The Columbus, Mt. Sterling & Washington Electric Railway Company was lately incorporated by C. P. West, W. R. Smith, F. Johnson and H. K. Stewart. The object is to construct and operate an electric railway, commencing at Washington Court House, and passing through Madison Mills, and Mt. Sterling, terminating in this city.

Pittsburg, Pa.—The Langton Electric Company suffered a considerable loss in a recent fire in this city.

POWER AND TRANSMISSION PLANTS.

Amsterdam, N. Y.—The Amsterdam & Hagaman Traction Company has purchased property and will erect a power station for the transmission of Schoharie Creek hydraulic power and will also establish a steam electrical power plant.

Peoria, Ill.—The Acme Harvester Company has lately contracted with the R. Lester Thayer Company of this city for a complete electrical power plant in its new works at South Bartonville. This plant will comprise 500 horse-power in generators and motors. The novel feature of the Acme plant is that it will be driven entirely by electricity.

Torrington, Conn.—It is reported that the E. A. Perkins Electrical Company of this place is negotiating for the purchase of the water privileges of Falls Village with a view to the development of a gigantic electrical power scheme which will affect all of northwestern Connecticut.

AUTOMOBILES.

Meriden, Conn.—W. W. Wheeler, president of the W. W. Wheeler Automobile Company of this place, has invented a motor for automobiles, and a company is being organized here for the manufacture of the same.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16⅜@16½c.; Lake, 16⅝@16¾c.; casting, 16⅜@16½c.

William L. Elkins denies the story that he is associated with Charles T. Yerkes in the London railway scheme.

To complete the authorized issue, the Bell Telephone Company will issue $1,000,000 additional capital stock.

The Mexican Telegraph Company has declared a quarterly dividend of 2½ per cent., payable October 13. Books close October 6 and reopen October 15.

J. Levering Jones of Philadelphia, and John B. Stauffer, of New York, have been added to the board of directors of the Erie Telegraph & Telephone Company.

The Anaconda Copper Mining Company has declared a dividend of $1.25 per share and 75 cents extra, payable October 27. Books close October 10 and reopen October 28.

The Erie Telegraph & Telephone Company has declared the regular quarterly dividend of 1½ per cent., payable October 8. Books closed September 29 and reopen October 8.

The Parrot Silver & Copper Mining Company has declared the regular quarterly dividend of $1.50 per share, payable October 29. Books close October 13 and reopen October 30.

The Wisconsin Telephone Company has declared the regular quarterly dividend of 1½ per cent., payable October 8. Books closed September 29 and reopen October 8.

The Michigan Telephone Company has declared the regular quarterly dividend of 1½ per cent., payable October 8. Books closed September 29 and reopen October 8.

The Central & South American Telegraph Company has declared a quarterly dividend of 1½ per cent., payable October 6. Books closed September 29 and reopen October 8.

The latest quotations for some of the new industrial stocks, not given elsewhere, are: Electric Boat, 13@17; New York Electric Vehicle Transportation, 6½@7½; New England Transportation, 3@3½.

Advices from Montgomery, Ala., state that consolidation has been effected between the local street railway companies and electric companies. It will be bonded for $2,100,000 and its capital stock will be about $3,000,000.

The inability of the directors of the Chicago Union Traction Company to obtain a quorum on Friday last necessitated a postponement of action on the dividend and the election of officers until October 4.

The New York Rapid Transit Commission on September 27 by a unanimous vote decided to tunnel the East River and connect the two boroughs by an underground road that shall act as a feeder of the main subway system in Manhattan and the Bronx.

At intervals for several years past the directorate of the Toronto Electric Street Railway has tried to buy out the Metropolitan Electric Railway, which also operates in the city of Toronto and environs. Negotiations are now under way with good prospects of a successful issue.

The annual meeting of the Standard Light & Power Company of Montreal, Que., was held in that city on September 26. The annual report showed the company to be in a very prosperous condition, having declared for the year an 8 per cent. dividend, and after providing for unforeseen contingencies, were able to add to profit and loss account over $10,000.

A cable dispatch from London says that Charles T. Yerkes has closed his deal for the purchase of the franchise of an underground railway running from Charing Cross to North London, and he has been elected chairman of the company which will construct the road. The English company now passes into American hands. Mr. Yerkes paid $500,000 to cover the capital sunk by the English promoters of the company. The resignations of the original board were simultaneously recorded and a new board was selected. The new road will be equipped with all the latest improvements in electrical transit.

The fight between Mr. Keene and the Whitney-Widener-Elkins syndicate over Brooklyn Rapid Transit promises to be as interesting as their contest over Third Avenue last year. It is generally believed that Mr. Keene lost heavily in the Third Avenue collapse. Mr. Keene, it is said, is now trying to prevent the Metropolitan syndicate from playing very much the same game in Brooklyn Rapid Transit. It is said that the Metropolitan interests are trying to force the stock down to 35, buy it in at that price and reorganize the company on the basis of one share of new stock for two of the old. Keene is trying to force the company to pay more than 50 for its stock. There is said to be a big short interest in the stock and it may be bid up suddenly at any time.

Steam railroads in New England, says the Boston "News Bureau," are gradually entering the electric railway field as a counter move to offset electric road competition and for the purpose of adding "feeders" to their systems. The New Haven Railroad was the first to branch out in this direction and it has acquired considerable electric road mileage in pursuance of this policy. The Boston and Maine has likewise entered the electric field. It has constructed at Portsmouth, N. H., an electric road 16 miles in length, operating through the streets of that city and through outlying towns. The Boston and Maine has now asked for authority to build an electric road between Nashua and Concord, N. H. President Lucius Tuttle of the Boston and Maine says: "We have been operating an electric road at Portsmouth, N. H., for about two years with good results and if granted authority will probably build between Concord and Nashua. In New Hampshire we have the right to build electric branches, and we are taking advantage of that right, as fast as the necessity arises, by building feeders for our steam road."

ELECTRICITY.

Vol. XIX. NEW YORK, OCTOBER 10, 1900. No. 14

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES, - . - -	$2.50
IN CLUBS OF FIVE OR MORE, - - .	2.00
FOREIGN COUNTRIES, - - - - -	4.50
SINGLE COPIES, - - - - - -	10 cents

Remit by Express, Money Order, Draft, Post Office Order or Registered Letter.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter

EDITORIAL NOTES.

The Disposal of Town Refuse.

A paper of great practical importance on the subject of the disposal of town refuse, was read by Mr. McTaggart a few weeks ago in England, at the Bradford meeting of the British Association for the Advancement of Science. Among other things Mr. McTaggart pointed out that although the varying nature of the refuse, and the consequent variation in the calorific value rendered it, to say the least of it, impolitic to combine refuse destruction and electric lighting in one plant, it is quite within the range of practicability to utilize the residuum after incineration for the manufacture of bricks and tiles, engine foundations, sand, and so on, at such a cost as to make the operations a financial success. This he has done at the Bradford works, where a large number of destructors have been doing service for many years past, and more are now being added. The experience that Mr. McTaggart has, influences his remarks that the two operations of electric lighting and refuse burning should be separate and absolutely distinct the one from the other. That will prevent any mutual handicapping, and will tend to the development and up-to-dateness of both. The refuse collected at Bradford and other towns has shown that its varying nature at different times in the week renders it necessary if a definite large amount of electrical energy is to be available when required, that coal would have to be called in to assist the refuse or possibly to take its place. So far as the Bradford undertaking is concerned the waste gases are used in connection with the electric lighting of the works themselves and the roads adjoining, but nothing more. What they are doing is to develop the destructor as a destructor on right lines, afterwards making profitable use of the remaining clinker for the manufacture of bricks and other things at so low a cost that the selling prices are greatly below the current market prices for these materials. Mr. McTaggart's opinion is that in this way more satisfactory results will be obtained than by the mere generation of electricity by the aid of the waste furnace gases. As Mr. George Watson says, a destructor is not by any means an automatic machine. It requires a man of skill at the helm.

Pacific Cables.

One of the first questions to demand the attention of Congress at its coming session must be, by all the exigencies of war and peace, the trans-Pacific cable; certainly no one in favor of the bill could have possibly planned circumstances that would more forcibly have made the necessity for it clear to the public and private mind than those that have transpired during the present summer when this country has been placed diplomatically and commercially at the mercy of the world in general.

The question of the practicability of such a line has been clearly demonstrated, and it is understood that Rear-Admiral R. B. Bradford, in his forthcoming report, will recommend that Congress be urged to make an appropriation for a cable across the Pacific. A survey of the Midway Islands has been completed by the Iroquois, and there is no doubt of the value of the islands as a site for a cable station. The bed of the ocean has been completely surveyed from San Francisco via Honolulu, Midway Islands and Guam, to the Philippines, and from Guam to Yokohama. It is certain that unless we take some action in the immediate future Great Britain will step in and build a line to extend from the western coast of British North America through the Pacific and down to the Australasias. In fact, a recent issue of the London "Electrical Review" contains the specification for the proposed Pacific cable which is divided into three sections. The first is that of the Vancouver (Port San Juan)—Fanning Island cable, which has a total length of 3,653.5 nautical miles, all of this being main cable with the exception of 64½ nautical miles of heavy shore end, heavy intermediate and light intermediate. The conductor will be composed of a central copper wire surrounded by smaller ones, weighing altogether 600 lbs. per nautical mile, and having a resistance of not more than 2.03 B.A. ohms at a temperature of 75° F. It is to be insulated with three or more coatings of gutta-percha weighing 340 lbs. per nautical mile.

The dielectric, after 1 minute's electrification, is not to have a resistance of less than 500, nor more than 1,500 megohms per nautical mile at 75° F., and its average inductive capacity is not to exceed 0.440 microfarad per nautical mile. The shore end and intermediate core is to be sheathed with brass tape, but the core for the main cable is not so protected.

The second contract is for the Fanning

Digitized by Google

Island—Fiji (Suva), length totaling 2,181 nautical miles, composed of 8 miles heavy shore end, heavy intermediate and light intermediate; 649 miles of heavy deep sea, and 1,524 miles of light deep sea cable.

The conductor weighs 220 lbs. per nautical mile, and is composed of a central copper wire surrounded by smaller ones, having a resistance at the usual temperature adopted in cable testing of not more than 5.54 B.A. ohms.

The gutta-percha covering weighs 180 lbs. per mile, insulation resistance as in the previous case, with an inductive capacity not exceeding 0.385 microfarad per mile. The short lengths are brass sheathed as before.

The third contract comprises the following sections: (a) Fiji (Suva)—Norfolk Island (Sydney Bay); (b) Norfolk Island (Sydney Bay)—Queensland (Moreton Bay); (c) Norfolk Island Sydney Bay) New Zealand.

(a) has a total length of 1,019 miles, all but 50 being deep sea. (b) a length of 906 miles, of which 852 miles are deep sea. (c) 513 miles, 440 being deep sea, the grand total under this contract amounting to 2,438 nautical miles.

The core of all three sections is 130 lbs. copper and 130 lbs. gutta-percha per mile, the conductor consisting of a strand of seven copper wires. The insulation resistance is to be as in the two previous contracts, and the inductive capacity shall not exceed 0.355 microfarad.

One drawback to the speedy construction of an American cable would seem to be the conflict which has been going on as to whether the proposed cable shall be laid and operated by the Government or by a private corporation. Generally speaking, in this country municipal or Governmental control of such an enterprise is not to be recommended, but rather than have this important matter held in abeyance it would seem even preferable to have the cable laid by the Navy, even though it were ultimately to be operated by the Post Office Department.

* * *

An Automobile Show for Washington.

It has been amply demonstrated that there is no factor so potent or so effective in the work of popularizing the automobile as to show the public this type of vehicle in its finished state, and to have them see for themselves the degree of perfection that has been attained by the automobile manufacturers of this country. Believing this can best be done through an exhibition, a number of prominent business men of Washington, D. C., have arranged to hold a show in that city during the week of December 10, which will be known as the National Automobile and Sportsman's Exhibition. Convention Hall, a massive building without a single pillar and and having a floor space of 36,000 square feet, has been secured for the show, and will be divided in such a manner as to provide for 110 spaces. A track 16 feet wide and an eighth of a mile in length will also be constructed in the building, where practical demonstrations of the efficiency of the various vehicles exhibited can be made. This will be the first automobile show to be held at the National capital, and no expense will be spared in making it an unqualified success.

The public of Washington is gradually awakening to the practicability of the self-propelled vehicle, and the promoters of the proposed exhibition believe that no better opportunity of reaching a large class of interested people can be had than a good representation at the forthcoming exhibition. Congress will be in session at the time, and the Washington season will be in full swing. The officers of the exhibition are as follows: Edward Reynolds, manager; W. J. Foss, treasurer, and Rudolph Jose, secretary.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A NEW dynamo of 500 horse-power has lately been put in at the State penitentiary near Nashville, Tenn.. Electricity furnishes the motive power in all the factories and about the prison.

ELECTRICITY has proven the woman's friend at St. Etienne, France, where it now runs 5,369 ribbon looms in 2,380 weaving shops. The looms were formerly worked by hand, and could be operated only by men, but under the new conditions women can readily do the work.

THE new building of the Ottawa Carbide Company of Ottawa, Ont., contains some of the finest machinery on the American Continent, and is capable of producing sufficient carbide to supply a very large share of the needs of the world in this commodity. To describe the interior of the big building is at present impossible as no outsider is yet allowed within its walls for the reason that the machinery comprises, it is said, several valuable improvements which have not yet been patented, and new processes that are alone known to three or four principals. It is intended to run the works continuously night and day, having three shifts of workmen, so that a very large output of carbide seems assured. The construction of these works is estimated to have cost over $500,000.

THE Apple River electric power was turned on the St. Paul, Minn., lighting system last week. The company now has ten converters in place in the basement of the new power house, and others will be installed. These converters will convert the alternating current into a continuous current, suitable for domestic use in St. Paul.

IT is announced that direct telephonic communication will be established between London and Brussels at the beginning of next year at the charge of $2 for three minutes' conversation.

ACCORDING to a consular report, the three large German electrical companies, Messrs. Siemens & Halske, the Union, and the Allgemeine Electricitäts Gesellschaft, have founded a company bearing the title "Abwarme Kraftmaschinen Gesellschaft" for the exploitation of patents to utilize the waste of exhaust steam and condensing water. The report states that should the invention fulfill the expectations of its projectors, especially with regard to machines of large dimensions now in course of construction, "it will lead to a most important, in fact epoch-making, progress in the economy of central power plants."

THE New Haven, Conn., and Derby Road will be equipped with electricity within the coming year, and a start made to build an extensive electric railway system connecting New Haven, Derby and Bridgeport. There is now in process of construction on Long Wharf in New Haven, an electric plant, which will be capable of producing 3,000 horse power. The plant for the present will be operated simply to light the local offices and station building, but it is being fitted up with apparatus to generate and conduct electric power, and this will be turned into the Derby Road and used as the operating power for that line. The third rail will be used in preference to the overhead trolley, and the steam locomotives taken off and replaced by motor cars.

THE power house belonging to the Brooklyn Rapid Transit Company, located at Third avenue and Second street, in Brooklyn, was badly damaged by fire on the morning of October 3. The damage, it is said, will amount to about $35,000, which loss, however, is covered by insurance.

A CABLE dispatch from London to the N. Y. "Sun" states that on October 6, Marconi successfully transmitted a message by wireless telegraphy from Boulogne, France, to Dovercourt, a distance of sixty miles. The customary mode of receiving and transmitting the message, by means of vertical wires, was abandoned, the dispatch being received on a cylinder only four feet in height.

ELECTRIC busses were lately put in operation at Wilkesbarre, Pa. They run on regular routes, fifteen minutes apart, and the fare is five cents a trip.

A STRONG effort is to be made to get for Indianapolis, Ind., the headquarters of the International Brotherhood of Electrical Workers, now located at Rochester, N. Y., and although the next convention will not be held for over a year, the members of local Union No. 10 have already started the campaign by soliciting the aid and votes of the other cities. President Wheeler is much in favor of the establishment of headquarters in Indianapolis on account of its central location and its railroad facilities.

PEORIA, Ill., will have the seventh convention of the International Association of Municipal Electricians, due to the efforts of City Electrician Michaels, who returned from the convention of the Association held at Pittsburg a short time ago, at which the matter came up for discussion, and has received the personal promise of most of the delegates that Peoria shall have the meeting of 1902.

THE Mikado's palace in Japan is connected by telephone with all the Government offices in the land; the electric light has been established there, and, to the immense satisfaction of the Japanese, there are dynamos at work in the imperial house that were made by Japanese workmen.

IN a paper read before the Paris Electrical Congress, Mr. Kellar gave a good general classification of the electric furnaces employed at the present time. There are three classes—arc furnaces, resistance furnaces, and incandescent furnaces. In the first class the heat is generated by a voltaic arc. In the resistance type the heat is furnished by the passage of the current through imperfectly conducting material, and in the incandescent furnace the material to be acted on is not initially conductive and a special conducting layer is required to start the current. The temperatures

Digitized by Google

obtained in the electric furnace are said to be in excess of 3,000 degrees C., and are the highest yet attainable artificially.

The Cooper Union schools of this city opened last week with full attendance in all the departments. Extensive changes and improvements have been made, one of which is the enlargement of the chemical laboratory, which will now accommodate 300 students, and the establishment of the day schools in chemical analysis, civil, mechanical and electrical engineering. The physical laboratory is equipped with steam, gas and electric motors, and with every variety of electrical appliance.

IT is stated that negotiations are about to be reopened between the Navy Department and Mr. Marconi, the inventor of the wireless telegraphy system, for installing the system on board ships of the United States Navy. The previous negotiations came to an end because the department regarded the price named by Mr. Mareoni for the use of his system as excessive.

GROUND was first broken for the great electric power tunnel plant at Niagara Falls, N. Y., October 4, 1890. During the first decade there has been a far more wonderful development than even the most sanguine anticipated. Factory after factory has been erected, plant after plant has come to the Falls to become a part of the new industrial growth made possible by the wonderful enterprise of the Niagara Falls Power Company. Buffalo, Lockport and the Tonawandas are to-day sharing the benefits of the Niagara power development and the fame of the installation has gone around the world. Men from the East, West, North and South have traveled across country to look upon the wonderful dynamos, and they have traveled on cars forced by power from this installation. Ten years ago there was expectation. To-day there is realization, and this realization is so rich in its wonders, in its accomplishments that it must of necessity cause blushes on the faces of those who a decade ago felt that the stupendous project of the Niagara Falls Power Company was not likely to mature in all the ripeness and richness predicted.

THE Colorado Electric Company, with head offices at Colorado Springs, Col., is at present very active in aiding the vast development of the gold camp at Cripple Creek. It is constantly supplying mines with electric hoists, and it has recently received more applications for electric hoists from Cripple Creek companies than in several weeks before. It is now having the line surveyed to carry the power to Beacon Hill, and has just decided to put up poles and wires to accommodate the many mines which are soliciting the power on Squaw Mountain.

THE following abstract, which appears in the "Journal" of the Chemical Society, is of a paper contributed by Mr. S. Skinner to the "Proceedings" of the Cambridge Philological Society, says the "Electrical Engineer," London. The abstract is as follows: "When a solution of potassium permanganate is electrolyzed with a carbon anode, 77.86 per cent. of the gas liberated at the anode consists of carbon dioxide, the rest being carbon monoxide and oxygen. The total volume of gas liberated is nearly the same as the volume of oxygen liberated by the same current in a dilute sulphuric acid voltameter. The permanganate ion persists in solution even although a quantity of electricity more than sufficient for its complete decomposition is passed through the cell. The author finds the electrochemical equivalent of carbon to be three times that of hydrogen. A cell may be constructed with a carbon rod in potassium permanganate, and a lead peroxide plate in dilute sulphuric acid, the two electrolytes being separated by a porous pot. The emf. is 0.33 volt, and acts externally from the lead peroxide to the carbon. In this self-acting system carbon is consumed at the ordinary temperature.

THAT electricity is apparently becoming popular in the South American countries as a motive power for railroads there is no doubt. The Chilian Electric Tramway & Light Company, at Valparaiso, which has some forty-two miles of horse-car lines, is to shortly convert them into electrical. La Capital Tramways Company, of Buenos Ayres, Argentina, has acquired the systems of the New and Grand National Tramways Companies, and intends to convert both of these systems into electric traction. It is well to bear in mind that La Capital Company has already a great deal of American material in use on its existing lines, and, under equal conditions, they give American manufacturers the preference.

ACCORDING to reports current among automobilists, a number of record runs will be made this fall between Newport, R. I., and this city. W. K. Vanderbilt, Jr., it is said, will make another attempt, while J. Dunbar Wright will also undertake the run.

AN association has been formed for the protection of the water, electric light and gas companies of Arkansas, Iowa, Kansas, Missouri, Nebraska and Oklahoma. It is called the Water and Light Bureau of Information, and has its principal office in Kansas City, Mo. Mr. George M. Myers, of that city, has been selected as general manager of the association. Mr. Myers is personally interested in and manager of a large number of water and light companies, and has had experience in the operation of such companies.

THE Brooklyn Navy Yard electric light and power wires are all to be placed underground. The conduits to carry these wires between the new power station and the old plant controlled by the department of construction are now being laid. The new shops are being wired and equipped for electric power. The million-dollar machine shop which is in course of construction for the steam engineering department, will have many machines with individual motors. This is also true of many of the machines in the pattern shop just completed. All belting is done away with and the machines are run only when needed.

The Nature of Alloys.

Amongst the papers read at the recent meeting of the British Association at Bradford was one by Mr. F. H. Neville on the "Nature of Alloys." The paper, says the London "Electrical Engineer," contained an abstract of the report of the British Association Committee on the subject. Thus it was stated that most students believed that certain definite chemical compounds existed in alloys. To prove this, however, certain means must be adopted to abstract the particular compounds. Ordinary chemical means of isolation were of no use under the circumstances. Fractional solution was effective in some cases, and by means of it several distinct metal compounds had been isolated from alloys, such as platinum-tin, copper-tin, zinc-copper, and other compounds. Another method was by observation of the "freezing point"; the molten mixture was cooled down slowly, and the temperature noted at which solid matter began to separate from the liquid. This varied with the proportion of the constituents, and by making many observations with varying proportions, a curve could be obtained of these solidifying temperatures, any irregularity pointing to the formation of something other than a mere mixture. By this means many interesting facts had been indicated which had subsequently been rendered evident by examination under the microscope. Valuable and interesting results had been thus obtained, both in this country and abroad.

A remarkable instance of peculiarity was exhibited by mixtures of aluminum and antimony when all the mixtures froze at a higher point than either of the components, and showed two irregularities indicative of two distinct compounds. In these mixtures it appeared that the component that predominated to a considerable extent acted as a solvent to the compound formed with the other component; but as the proportion of the other component was increased the conditions became reversed.

A Young Electrician Killed.

John O. Donohue, a young Canadian electrician, who was pursuing a course in electrical engineering at the General Electric Works at Schenectady, N. Y., was instantly killed recently in the testing department of the company's works. At the time of the accident he was engaged in testing a 400 horse power generator. The power was shut off for a time while some mechanical alterations were made, and during this time Donohue fell asleep on some belting. The belt upon which he fell asleep transferred power from the large motor to the generator which he was testing. While in this dangerous position the lever was turned by one of the mechanics at work in the shop. The body was carried to a fly wheel where it was badly crushed. No blame is attached to any one in the matter, as no one could foresee the possibility of any one being asleep on the belting.

Educational.

It is encouraging to note what a prominent factor the night-schools are growing to be in the lives of thousands of young men who have, for various reasons, been deprived of the privileges of a complete day-school education. Noteworthy among these institutions offering such opportunities is the West Side Young Men's Christian Association of New York City (318 West 57th street). Here the very best instruction (both elementary and advanced) is given in science, arts, modern languages, technical instruction, mathematics, music and commercial branches. Especially strong is the work that is being done in drawing and the other technical subjects. Very carefully planned courses are offered in simple and advanced mechanical drawing, architectural work, also free hand and water-color instruction. The West Side Association is an aggressive institution and is anxious to place the very best instruction that is to be had within the reach of all.

THE USE OF THE DYNAMO AND STORAGE BATTERY IN TELEGRAPH OFFICES.*

BY W. J. CAMP,

Superi.tendent C. P. R. Telegraphs.

Previous to 1870, acid batteries of various kinds were used for main telegraph circuits, and the Daniel form of blue-stone battery for the locals, or sounder circuits. Between 1870 and 1874, what is known as the "gravity battery" was brought into general use. This battery is a modification of the Daniel cell, but the sulphate of zinc and sulphate of copper solutions are kept separate by the difference in their specific gravity instead of by means of a porous cup. This form of battery is very constant and requires but little attention as compared with the acid. To obtain the best results not more than two or three wires should be worked from each bank, although frequently ten or more are thrown on one bank of battery. When this is the case the results are unsatisfactory, particularly during wet weather, and when wires of different lengths are combined together. A separate bank is required for each duplex or quadruplex set, and also a local battery for each sounder circuit. It is true that, as each cell gives out about one volt emf., the exact power required for each multiple circuit or local can be very accurately adjusted by adding to, or taking off from the number of cells; and on this account, a great many chief operators raised ojections to dynamo currents. However, even this advantage has been compensated for.

While the change from acid to gravity batteries effected a great economy in maintenance, and improvement in the working of the telegraph wires, a much greater stride has been made by the introduction of the dynamo and storage battery in telegraphic work. I will deal first with main lines, and then with local, or sounder and transmitter circuits.

About 1880 dynamos were introduced by the Western Union Telegraph Company at New York for supplying current to the single working wires. The means for doing this are comparatively simple. Two dynamos are used, each of a voltage high enough for the longest wires; the positive pole of one and the negative pole of the other dynamo are earthed, and the opposite poles connected to two buss wires. The various single working wires are connected to these buss wires, according to the polarity required, through an artificial resistance for each wire. The Western Union in the United States, and both companies in Canada use incandescent electric lamps for these resistances. The Postal Company in the United States uses german silver wire wound on tin tubes, so designed that, should any heating take place, it is counteracted by a current of cold air which passes through the tube. Additional resistances were inserted on the shorter wires to make all lines approximately of the same electrical length. These resistances were usually of fine german silver wire wound on the handle of a wedge which was inserted with the instrument wedge in the spring-jack of the switch. It has been found much more satisfactory, however, to have several dynamos giving different voltages, and the use of the resistance wedges abandoned.

The next step was to apply dynamo power to duplex wires. For many years back the polar duplex has been used all over America. When using the gravity battery the transmitter (pole changer) was arranged to reverse the poles of a bank of battery from earth to line and vice-versa. This pole changer required very accurate adjustment in order to reduce the time of reversals to a minimum; the least break in the circuit, or short-circuiting of the battery, being liable to affect the signals at either or both terminals of the line.

For dynamo power the earth connection is omitted in the pole-changer; the armature is connected to the line circuit, the front contact to the negative buss wire, the back contact to the positive, and resistances of 600 or more ohms inserted ahead of each buss wire to prevent arcing at the contacts of the pole changer.

Then came the application of the system to quadruplex circuits. Great difficulties had to be overcome to effect this. Two entirely different systems are in general use, one by the Western Union and Great North Western Telegraph Companies and the other by the Postal Telegraph Company. The Canadian Pacific Company uses the Western Union system at Toronto and Montreal and the Postal system at other points.

A few general remarks with reference to the duplex and quadruplex as worked with gravity batteries may be of interest at this point to those who have not read up the subject.

Duplex is a system by which two operators can transmit simultaneously in opposite directions. This is attained by winding the receiving relays with two coils of wire in opposite directions, one winding being connected to the line, and the other to a set of resistance coils and condensers which are so adjusted that the electrical length and static capacity are the same as the real line. The home power divides equally, half passing around the core in one direction to the real line, and half in the opposite direction to the artificial line, the result being that the core is not magnetized by it, and it is not susceptible to the home power. As the power coming over the line from the distant station only passes through one of the coils, and there is none coming in from the artificial line to counteract it, the core is affected by any change in power at the distant station. The receiver is a polarized relay whose armature closes the sounder when moved in one direction, and opens it when moved in the other. The transmitter is an instrument worked by an ordinary telegraph key and local circuit. It is so arranged that, when the key is depressed the negative pole is connected to the line, and positive when the key is opened.

Quadruplex is a system by which two operators can transmit one way simultaneously with two operators transmitting in the opposite direction, i.e., four messages can be sent simultaneously on one wire, two in each direction. The arrangement by which two operators transmit in the same direction may be briefly described thus:

A transmits by reversing the polarity to line the same as in duplex, and C receives by means of a polarized relay. B transmits by increasing and decreasing the same power which A is reversing; D receives from him by means of a neutral relay which responds to power of any direction if it is strong enough. The retractile spring of the armature is adjusted so that the weaker power does not move the armature, but when the full power is on the spring is overcome. By double winding both receivers at each end, as explained for the duplex, we obtain "two circuits in the opposite direction."

In order to obtain satisfactory work all resistances must be maintained at their relative length. When using gravity battery transmitter "B" simply adds more cells to "A's" battery, or takes them off when closing or opening his key. A resistance coil to compensate for the internal resistance of the extra battery is automatically cut out, or inserted, thus maintaining the total electrical length of the line from earth to earth

The Western Union system of transmission is shown in Fig. 1. The resistance from A to

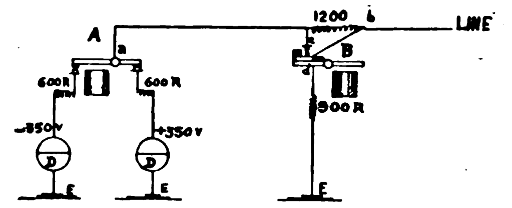

Fig. 1.

earth through the dynamo circuits is 600 ohms no mattter which position transmitter A is in. When transmitter B is closed the resistance from b to earth is 600 ohms because the 1,200 ohms coil is shunted out by contacts c and the leak of 900 ohms is disconnected at d. The full power of either the negative or positive dynamo goes to line through one of the internal resistances of 600 ohms. When the transmitter B is opened the 1,200 ohm coil is inserted between b and c making the total resistance between b and earth via the dynamo of 1,800 ohms. There is also another route to earth, through the leak of 900 ohms. The joint resistance of these two routes is 600 ohms, as found

$$\text{by the formula } \frac{A \times B}{A + B} \text{ or } \frac{(1{,}200 + 600) \times 900}{(1{,}200 + 600) + 900} = 600$$

thus maintaining the same resistance between b and earth for all changes.

The amount of power passing b to line is however reduced to $\frac{1}{3}$ when transmitter B is open, first, on account of the added resistance of 1,200 ohms, and second, on account of the leak of 900 ohms. In other words when transmitter B is closed the power passing to line is three times as much as when B is open.

By changing the added resistance to 1,800 and the leak to 800 ohms the difference is then as 4 to 1 and the internal resistance still maintained at 600 ohms.

The principle of the Postal system of quadruplex transmission is shown in Fig. 2. For

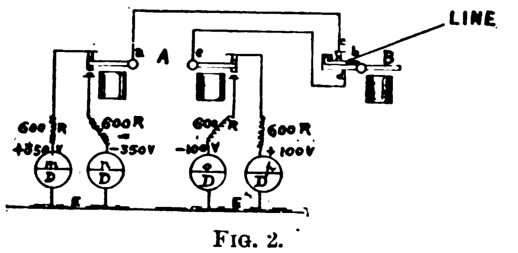

Fig. 2.

the purpose of explanation, transmitter A is shown as two separate instruments worked simultaneously by one key. The one on the left gives 350 volts to the line and the one on the right 100 volts. Opening of the key connects either m or p to line according to the position of transmitter B; closing of key connects either n or o; or opening A gives positive pole and closing gives negative. Closing transmitter B connects line through b, c, a, to dynamos m or n (350 volts) according to the position of transmitter A; opening transmitter B connects line through b, d, e, with dynamos o or p (100 volts). Thus B transmits by increasing

*Paper read before the Canadian Electrical Association, held at Kingston, Aug. 29, 1900.

Digitized by Google

or decreasing the power sent out by A. As the resistances in each of the four leads to the dynamos are the same (600 to 1,000 ohms) the internal resistance from b to earth is constant.

It is hardly within the scope of this paper to compare one system with the other. It is sufficient to state that either system has certain advantages and both give excellent results. The receiving instruments are the same as for gravity battery.

The dynamos are made of sufficient voltage for the longest quadruplex circuit from the office. When the same machines are used on comparatively short circuits a resistance coil of 1,000, or more, ohms is inserted between b and the receivers.

We now come to the locals. For ordinary sounder circuits a very simple plan is to use a dynamo of 6 volts and connect all sounders in multiple. The sounders are wound to 20 ohms resistance; but in nearly every office where dynamos are used there are also quadruplex or duplex sets, and it is often necessary to connect these as repeaters. There are a number of systems, but I will only decribe the one in use by the C. P. R. This is, I think, the most simple yet designed. It is shown in Fig. 3. Each half quadruplex or half

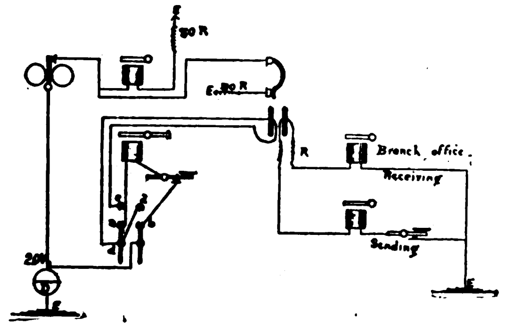

Fig. 3.

repeater is treated as a duplex set. All sounders and transmitters are wound to 20 ohms and, by resistance coils, each local circuit is brought up to 100 ohms. The dynamo gives from 20 to 25 volts. The former is found to be sufficient. The figure shows the instruments in a normal position, except that the transmitter wedge should be inserted in a spring jack. Starting from the dynamo the receiving circuit passes through the relay contacts, 20 ohm sounder, 80 ohm coil, earth to dynamo, the leg through jack being open at c. The sending circuit is from dynamo through switch b, key, 20 ohm transmitter, switch a, d, wedge, back contact of jack, 80 ohm coil, earth to dynamo.

To work as repeaters the wedges of the two sets are exchanged, that of No. 1 set, being inserted in No. 2 jack and No. 2 wedge in No. 1 jack; the table switches a and b on each set are reversed.

The circuit then is, earth, dynamo, relay contacts, 20 ohm sounder, 80 ohm coil, earth; also from relay contact to top of jack, front of wedge of No. 2 set, c, a, transmitter, key, b, d, back of wedge, coil and earth. The circuits from No. 2 set are the same. Any break in contacts of relay opens its sounder and also the transmitter of the other set. Thus signals received from the line on No. 1 set are automatically retransmitted over the line connected to No. 2 set, and vice-versa.

To extend the locals of a duplex to a branch office, the loop wedge is inserted in the spring jack on top of the transmitter wedge; switch a is turned up, switch b down. Circuits are then as follows: Receiving side, dynamo, relay, sounder, coil, earth; with leg from relay contacts to top of jack, front of wedge, coil, line, branch receiver and earth. The resistance coil is adjusted so as to make the circuit from wedge to branch earth total 100 ohms including branch sounder.

Sending side, dynamo, b, key, transmitter, a, c, front of transmitter wedge, back of loop wedge, coil, line, branch sounder, key and earth. The resistance from wedge to distant earth is 80 ohms including sounder. On this circuit the resistance of the transmitter is added making a total of 100 ohms.

Sometimes the dynamos are operated from a common shaft driven by an electric motor or other power, but the plan most generally adopted is to use motor generators, each machine working independently. In order to be reasonably certain of a continuous supply of power spare leads are run to different power stations, and spare machines are also kept in readiness, so that not more than a minute or so is lost at any time.

In cities where continuous power cannot be obtained from two different stations, storage batteries are now largely used. Generally speaking, the wiring of a telegraph office, from the discharge leads of a storage battery to the instruments, etc., is the same as for dynamos, but extra switches have to be used for connecting the various banks of battery with the charging or discharging circuits. Various devices are used, but as I consider the C.P.R. system the most flexible, I will describe it only.

At Vancouver the Winnipeg street railway power is transformed by two motor generators; one reducing the power to seven volts of twenty amperes capacity for charging local batteries; and the other to 130 volts, 5 amperes, for main batteries. In Ottawa a 250 volt power is reduced to seven volts for the locals and the mains are charged direct without reduction. In St. John the 114 volt lighting circuit is used. The locals are in two banks, of two cells each, of chloride accumulator, type E 9, one bank being charged while the other is discharging. There is no dead resistance inserted in the local circuits, as is the case where dynamos are used, extra cells providing the necessary power when quadruplexes or duplexes are extended at branch offices.

The switch for the main batteries consists of a series of spring-jacks and wedges, so designed that the jack is open, and a wedge cannot be inserted when reversed. The cells (which are C 3 type of accumulator) are arranged in banks of 40 or more as needed to meet the requirements of the office, and of a voltage sufficiently below the charging circuit. The negative pole is connected to the top of a wedge and positive to bottom. The wedges are all interchangeable. As many banks as required can be charged simultaneously.

In Canada, the C.P.R. has storage battery plants at Vancouver, Winnipeg, Ottawa and St. John, and dynamos at Toronto. The new Telegraph building in Montreal will also be equipped with dynamos. At present power in the latter place is obtained from the dynamo plant of the G.N.W.Tel. Co. I understand that the W. U. and G. N. W. Companies have storage plants at St. John, Quebec, London and Ottawa, and dynamos at Toronto and Montreal.

The adoption of either dynamos or storage battery for power on telegraph line has very materially improved the working of the lines, and at the same time effects a great economy. One or the other will gradually replace gravity batteries for all main lines, and the time may come when even the locals at wayside stations will be worked by storage battery cells which will be charged at some central point and sent out by train.

AN EXPLANATION OF A COMMON PHENOMENON NOTICED IN CABLE WORK.*

BY H. G. BARWELL.

It has probably been noticed by every electrician who has been engaged in cable work that during the whole time a splice is being made sharp kicks are noticed on the galvanometer employed for the usual dielectric resistance test.

On a recent repair, while picking up to a fault, a watch was kept for it coming in by means of a current direct to line through a milliammeter, to which was joined one side of a telephone receiver, the other side of the latter being connected through a 1 microfarad condenser to earth (as per Fig. 1). The current ob-

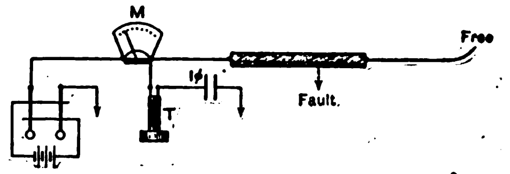

Fig. 1.

served on the milliammeter was 40 milliamperes. On commencing to pick up, the sound in the telephone was found to be intermittent—that is to say, there was alternate buzzing and silence, the cause of which I take to be as follows: The depth of water was 980 fathoms; 480 fathoms from the ship was a splice, type C to D, the latter type having each sheathing wire taped. The fault, which was two nauts beyond this splice, was caused by a wire of the type D having punctured the core at a bad twist, the iron wire remaining in the hole and apparently completely stopping any contact between the copper conductor and the water, as was shown by the fact that the resistance of the fault remained extremely steady at some 40 ohms and exhibited no signs of polarization with either current. It was evident, therefore, that the fault was in no way responsible for the intermittent buzzing in the telephone, and that it was probably caused by the ship rising and falling on the fairly heavy swell and bringing varying strains upon the splice, which at the commencement of picking up was about midway between the surface and the bottom. On the splice coming over the bow sheave, the buzzing became considerably louder, and continued, without any intermission, until it had passed the jockey, when, on stopping the drum to cut the cable, the noise ceased entirely. Instructions were then given to get the splice on the drum and worry it, and then to lay it on the deck again. This operation was repeated several times, and on each occasion the moment it was handled, buzzing recommenced, but stopped instantly on its being left alone. After cutting out the splice, its insulation was tested and found to be perfect, within the limits of observation. The telephone was then connected to the sea end containing the fault, and found to be absolutely silent, showing, as before stated, that the fault was in no way responsible for the buzzing. The milliammeter

* From the "Electrician," London.

Digitized by Google

meanwhile had remained perfectly steady at 40 milliamperes, exhibiting no signs whatever of any variation of the resistance in circuit.

This phenomenon appears to be of the same nature as that mentioned in my first paragraph; and I offer the explanation that it is due to small changes in the capacity of the cable caused by variations in the resistance of the contact beween the respective sheathing

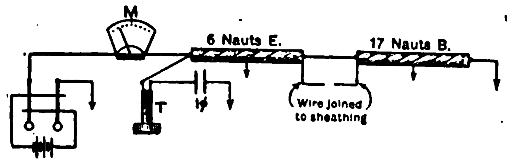

FIG. 2.

wires at a splice, these variations being due to the application of different strains or pressures, and that the effect is more noticeable when, as in the above case, one of the cables has each of its sheathing wires covered by a partially insulating tape.

As a proof of this the following experiment was tried: Six nauts of type E in one tank, and 17 nauts of type B in another, had their conductors joined together, and their sheathings brought into better electrical contact by means of connecting wires, as shown in Fig. 2.

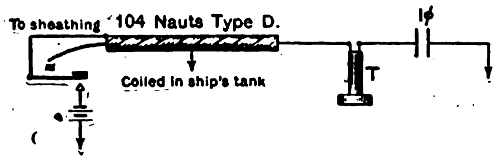

FIG. 3.

On tapping the ends of these connecting wires together a very distinct tap was heard in the telephone, which was equally audible when no current was being sent through the cables. One of the wires was then connected to a file and the other wire scraped over it, when it was observed that the sound in the telephone was very similar to that produced by handling a splice, being more of a buzzing than a distinct tapping. By this means Morse signals could be clearly read, although, as before mentioned, no current was being sent through the cables. The distant end of the type B was then freed, and a galvanometer put in place of the milliammeter, and on tapping the ends of the wires

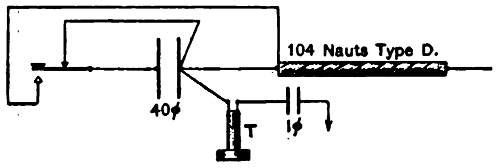

FIG. 4.

together kicks, similar to those observed while a splice is being made, were produced on the galvanometer. This, I think, proves fairly conclusively that the kicks are due to changes in capacity. It will be seen from the above experiment how very minute the variations in the resistance of the sheathing are which disturb the surface charges, and cause these effects; as, in the above case, the two sheathings were already in good contact with each other through the ship's hull, before the ends of the copper wires were tapped together, and more especially so as a considerable portion of each length of the cable sheathing was devoid of any outer serving. These disturbances are, I think, caused as follows: When two lengths of cable are spliced together, they take up charges which vary according to the respective localities along their length, and possibly also in proportion to the size of their cores, and rates of absorption, etc. Now, if any alteration is made tending to improve or the reverse the connection between their respective sheathings, the *status quo ante* is not maintained, and a redistribution of the free potentials takes place, producing the sound heard in the telephone. The two following experiments are also of interest.

A current was communicated to the sheathing of 104 nauts of type D, coiled in the ship's tank, to the conductor of which a telephone was connected, as shown (Fig. 3). On depressing the key signals were distinctly audible whether the home end of the conductor was freed or earthed, no difference being perceptible when the telephone was connected as shown, or to the home end.

Fig. 4 indicates the connections in the next experiment. It this two 20φ condensers joined in parallel had one of their plates connected to the core of the 104 nauts of type D, and also to one side of the telephone, the other plate being joined to the lever of the key, the lower contact of which was in connection with the cable's sheathing, and the upper to the opposite side of the condenser, so that the latter was short-circuited after each contact. With this arrangement sound signals were quite audible, but not so strongly as in the previous experiment; if, however, the telephone was connected to the far end of the conductor, nothing whatever could be heard. This effect was probably in greater part due to charges induced in the cable from the rolling of the ship, which were imparted to the condenser on depressing the key. These induced charges may also possibly play a part in the first experiment with the two lengths of cable, but I think there can be little doubt that the sounds are mainly due to the improvement in the contact between the two sheathings in this particular case, and the resulting redistribution of the free potentials.

From the foregoing it will be seen that by joining a telephone up as in Fig. 1 a splice can be heard when the ship is approaching it picking up, provided there is no other disturbing influence at work, such as a variable fault in the circuit; and knowing the depth of water, and noting the first indications of the splice being disturbed on the telephone, one may form a fairly approximate estimate of its distance from the ship.

ELECTRIC MINING MACHINERY AND LOCOMOTIVES.

BY FRANK C. PERKINS.

The various mining exhibits at the Paris Exposition show how important the subject is becoming, and the amount of energy used to bring this class of apparatus to the highest efficiency. The Paris exhibits shown in the illustrations, Figs. 1 and 2, of Sulzer Brothers., of Winterthur, Switzerland, and the American firm showing Jeffrey mining machinery and locomotives are particularly interesting. The firm of Sulzer Brothers not only shows electric boring machines in operation, but electric mining pumps, and electric ventilating apparatus. The American firm has not only its various mining machines on exhibition, but its

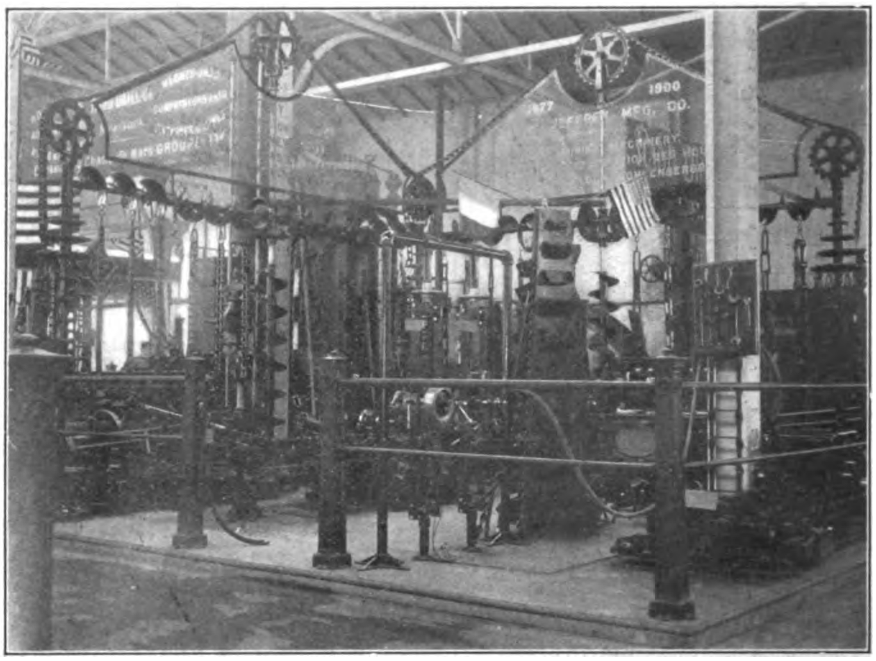

FIG. 1.—JEFFREY ELECTRICAL MINING MACHINERY EXHIBIT AT THE PARIS EXPOSITION.

mining locomotives operated by electricity were purchased and used by the Paris Exposition during construction for handling freight.

There are many uses to which electricity may be put in the operation of mines, but probably none are of more importance than that of the various haulage systems now employing electric locomotives.

The electric locomotive is especially suitable for mining work as it allows of extension and the many changes which are often necessary, while its great flexibility makes it particularly well adapted to this class of installation. It is built low and compact and can easily enter very small and narrow openings, while every part of the moving mechanism is enclosed and not exposed to injury. The mechanism is simple and the running parts are very accessible in case repairs are found necessary.

The mining locomotive shown in illustration, Fig. 3, has a draw bar pull of 3,500 pounds, and operates upon a 500 volt circuit. This machine is in operation in a mine in the Pittsburg district. The speed varies from six to ten miles per hour. There are two 40 horse power motors employed, and the total weight of the locomotive is about ten tons.

Digitized by Google

This type is also operated from the center. The motors are of the iron-clad multipolar type, the armature and field coils being thoroughly waterproof and carefully protected by the motor casing.

Electric mining locomotives are not usually rated in horse power terms, but are rated on weight, while the same wheels when badly worn may show a friction amounting to 65 or 75 pounds per ton weight.

Electric locomotives used in mines are usually rated to give their full power at about six miles per hour. The starting is made with a modified form of the usual type of railway

FIG. 2.—SULZER MINING MACHINERY EXHIBIT AT THE PARIS EXPOSITION.

the weight on the driving wheels which determines their tractive power. A great amount of resistance is offered to locomotive and train of cars on curves, which frequently are of very short radius, and many times occur on quite heavy grades. The calculations of curve resistance are generally made on a basis of one pound per ton of train weight for each degree of curvature.

controller, and with light loads and low grades a much higher speed than the above is attained.

In a recent issue of ELECTRICITY (April 25), a detailed description of the mining machinery operated by electricity in the coal regions was given with particularly interesting photographs of the machinery as actually used and operated in the mines. These machines are of the same general design as those exhibited at the Paris Exposition and need no further explanation.

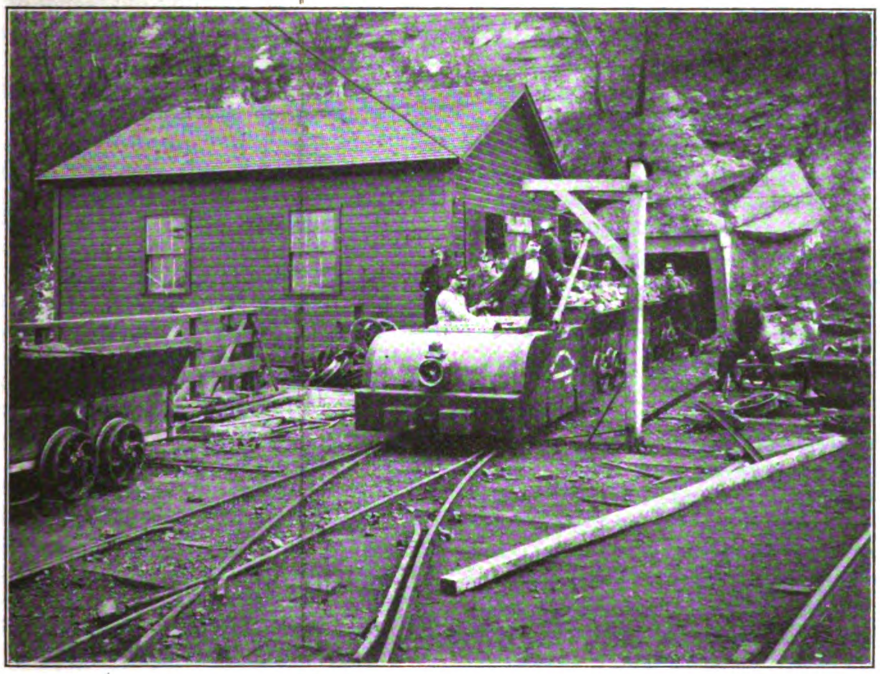

FIG. 3.—500-VOLT ELECTRIC MINING LOCOMOTIVE.

Mining wagons used for carrying coal have fixed axle and loose wheels and usually show from 25 to 35 pounds of friction per net ton

ELECTRICAL CONTACTS.*

BY F. C. MASON,
Superintendent Police Telegraph, Brooklyn, N. Y.

It is curious that the subject of Electrical Contacts has received so little attention in the literature and discussions of the general subject of electrical application. At the basis of nearly every variety of electrical apparatus, whether for signaling with small currents, or for the larger work of heating, lighting, generating and developing electric power and the application of electricity to chemical processes, the contact or point of discontinuity in the circuit is found as an essential part of the apparatus or of the method.

It is well, at this point, to say that this paper will be limited to those users of electricity employing relatively small currents, as in telephony, telegraphy and signaling, and will not touch on the larger field that its subject embraces in the utilization of heavy currents. However, the line of demarcation between the light current and the heavy current, is now by no means so sharply drawn as it was in the days when the primary battery, in one form or another, was the sole dependence of the telephone and telegraph engineer. When we see the motor-generators and the storage battery used as the central source of energy for a telegraph, fire alarm and telephone system, we naturally wonder for how long we can speak of the light current applications of electricity as a distinction from those employing large and powerful currents generated by dynamos.

Contacts may be roughly grouped into three classes: Those that are intended to be permanent (such as joints in wire and cables); those that are semi-permanent (such as contacts between wire and binding-posts), and operative contacts, or those that are intended to be opened and closed at will, as in keys, switches, etc.

To all these kinds of junctions, two enemies exist, constantly tending to destroy efficient electrical contact—chemical action and dirt. It is scarcely necessary to speak of mechanical strains, which are guarded against naturally by the exercise of common sense. Chemical action, as it applies to contacts, is generally due to remnants of some compound or chemical used in soldering, and to the action of air and moisture (either singly or in conjunction), producing oxidation of the surfaces in contact. This action is enormously enhanced by the formation of *sparks* at contacts of the operative kind, the resultant film of oxide being generally a non-conductor and interfering greatly with the operation of the contact. Dirt, as Emerson says, is merely "matter out of place." In electrical work, dirt means any non-conducting substance that interferes with good electrical contact. It is often dust, but in operative contacts is more frequently the products of oxidation of the points of contact themselves, where (as is too often the case) these are of the baser and more oxidizable metals.

Permanent joints, or contacts, are used both in line conductors and in instruments. Nowadays, the general introduction of hard-drawn copper wire for overhead line work, has reduced practice in this kind of jointure to a question of the best way to handle that material. Experience has shown that soldering such joints draws the temper of the wire, making a joint

* Paper read at the Fifth Annual Meeting of the International Association of Municipal Electricians, held at Pittsburg, Pa., Sept. 25-27, 1900.

Digitized by Google

of mechanical weakness, while the ancient habit of linemen, of twisting the wire at the joint into tight spirals, leads to the same result. For these reasons, the twisted and soldered joint must necessarily give way to one of the various and excellent types of tubular joint now manufactured for the purpose. In cable work, especially, where paper insulation is used, the best practice now, strangely enough, is to use merely the twisted joint without solder. The wire being soft and subject to no strains, the joint is abundantly strong; while its sheathing, after jointing, fully protects it from the harmful action of the atmosphere and moisture. To solder such a joint would merely add the danger of corrosion from the dissolving action and slow electrolysis of the fluxes used.

Permanent joints, in switchboards and instruments, being protected from the weather, are generally soldered. The wires used should be tinned, so as to leave no excuse for the use of the mischief-making chemicals sold as "soldering solutions." Tubular solder, having resin or stearine flux in its hollow part should be used and the utmost watchfulness employed to keep the acid and "salts" away from the work. One easy joint made by these means may plant the seeds of trouble to be reaped later, and by the peculiar provision of fate, almost invariably just when trouble or break-down is most to be feared.

Semi-permanent contacts are, practically, of only two kinds—binding-posts and fuses. The average American binding-post is a piece of metal with a hole drilled through it to receive the wire and another drilled and tapped to receive a set screw, which may or may not have a pointed end. The design of this type of binding-post is utterly vicious. The screw may shear the wire nearly in two, leaving it so that the slightest strain will break it off, or it may not come down to a tight-bearing on the wire, leaving a loose joint ready to collect dirt and become inoperative. Much the better type is that variety of binding-post in which the wire is firmly held between two flat surfaces, thus ensuring a large area of contact, and which is provided with a lock-nut, so as to avoid any danger of the binding washer working loose. In instruments having binding-posts of the other type, considerable improvement can be introduced by putting small hexagonal nuts, a little larger than the driving heads of the binding screws, on the latter and setting them down firmly on the top of the post to act as lock-nuts.

In fuses, which are an absolutely necessary part on any installation in a modern city traversed by electric light and railway conductors an excellent opportunity for bad contacts presents itself. The practice of securing the fuse-wire under a washer or the head of a screw is very bad, as the wire is strained, is apt to be reduced in section at some point, and cold flow of the fuse may take place. To obviate these troubles, it is usual to attach pieces of copper to the ends of the fuse-wire, screwing these down tightly under the binding washers. If the fuse, as is too often the case, is merely squeezed into the copper end, the trouble is only transferred to another point. Hence, the best solution of the fuse difficulty is to use copper lugs, to which the fusible wire is securely soldered, held down by screws provided by lock-nuts. Care should be taken in installing fuses not to set them in place under strain, as their expansion and contraction under temperature changes, produces crystallization of the metal or reduction of its cross section at some points.

While the two classes of contacts already referred to are, in a large measure, in the hands of the operating force of a fire-alarm, telegraph or telephone installation, the third class, and the most imporant to all of us—the working contacts of instruments—are confined to these structures and their nature is determined by the manufacturer. In keys, relays, vibrating gongs, the switching apparatus of the telephone station, and in all other places where signaling circuits must be made and broken, sparks will be formed, and no practical device known to the art can prevent their formation. While dust, always inimical to good contacts, can be excluded from such places by proper construction of the instrument, nothing will prevent the formation of oxides at the point of sparking, which is also the point of contact, except making these points of some material that will not oxidize.

For this purpose, the only substances known that are at the same time good conductors of electricity and possess the necessary qualities of mechanical strength, are platinum and a few other of the rarer metals, such as iridium and gold. The consensus of opinion and experience has shown platinum or certain of its alloys to be the only substance commercially available for the construction of contact points of this character. Unfortunately, platinum is a material of such great value that the expense of such contacts is greater than that of any other kind, and, therefore, the temptation of the manufacturer to replace such contacts with those of cheaper material, or to stint the size, has been very great, and too often he has fallen before it. He has introduced contact points of the baser metals in his instruments and this has far too often invited, if not assured, disaster.

Blame for substitution of such cheap contacts cannot rest entirely upon the manufacturer, so long as the users of electric signaling apparatus fail to recognize the value of the higher-priced article, or recognizing it, fail to specify its use when awarding contracts, and to see that this vitally important detail has been honestly and intelligently executed in the completed instruments.

Pure platinum is a very soft metal, and therefore is not as serviceable for contacts subject to mechanical blows as certain alloys of the metal with other members of the platinum group of metals. The production of platinum alloys specially adapted for contact under all conditions of current density and temperature has been very carefully investigated by Baker & Co., the platinum refiners of Newark, N. J., who now regularly manufacture a number of alloys possessing all the requisite properties for durable and perfect contacts. Their "XXV" brand is especially designed for use in electric signaling apparatus, and is now generally specified in awarding contracts for high-grade instruments.

For commercial reasons, the composition of this and other alloys is kept secret: but as to the operative value of contacts made from these alloys, I can say from personal observation that too much credit cannot be awarded this firm for their conscientious efforts to produce an article so vitally important to the certain operation of signaling apparatus and which fully meets our exacting requirements.

In municipal work, more than in any other, the electrical equipment must be absolutely reliable. A bad contact, sticking together or full of oxides may mean loss and danger of the gravest sort to the community. Through failure of the fire apparatus to respond to an alarm, or of the ambulance to answer its call, or of the police to appear promptly when summoned, a bad contact may exact a fearful toll in conflagration, or death or riot. And, in the saving of a few cents' worth of platinum the vast expenditures of municipalities for fire and police protection and of the generous public for hospitals, may be nullified. There is no room for economy of this wasteful kind in instruments upon which so much depends and to which, owing to the careful and conscientious superintendence of the members of this Association, the public looks with perfect confidence for perfect results.

THE ETHICS OF INSULATING MATERIALS.*

BY J. WRIGHT.

It is not my intention here to discourse upon insulating materials in general, but rather to confine my remarks to a consideration of those substances, chief amongst which are india-rubber and gutta-percha, so largely employed for the insulation of electric cables and wires.

The growing scarcity of the above-mentioned commodities recently led to a short general article in a contemporary from the pen of Mr. Terry, an authority of note on the subject, in which the writer comments upon the various substitutes for rubber and gutta-percha which have been introduced to a greater or less extent during the past few years.

It is not by any means so easy a task as would appear at first sight to obtain a satisfactory substitute for rubber and gutta-percha in the insulation of cables. It must be remembered that flexibility, combined with mechanical strength, and resistance to the passage of electric currents of varying tension, disruptive or otherwise, to say nothing of absence of porosity and durability under extremely variable climatic conditions, are but few of the many essential properties which must be possessed in the requisite degree by the substitute. India-rubber, or caoutchouc, as we all know, is a gum obtained from the sap found in the middle layers of the bark of certain trees indigenous to South America, Africa and the East Indies. It exudes on an incision being made in the bark for the purpose, and is collected by the natives of the locality in various ways. The main object aimed at, however, whatever be the manner in which it is undertaken, is to procure the coagulation of the rubber by exposing it in thin layers to the smoke of a wood fire fed with a species of nut also indigenous to the locality, and collected for the purpose.

If this drying be not properly effected, the rubber retains a certain compound which acts as a form of solvent and destroys it. This destructive agent is always present in a greater or lesser degree, and shows its presence in rubber which has been exposed to the atmosphere for a lengthened period, by converting it into a treacely mass contained by an outer oxidized crust which is extremely brittle.

The best, or Para rubber, when freshly procured, is extremely elastic, and has a generous modicum of "life," but, unfortunately, it is impossible to employ it in this condition for insulating purposes, as the impurities which all samples contain necessitate a somewhat severe

*From the "Electrical Review," London

Digitized by Google

course of washing and mastication in powerful machines specially designed for the purpose, which treatment decreases its vitality in a marked degree, but, at the same time, renders it, in the form of sheet or strip, of such consistency as to be suitable for applying to the cable.

Pure Para is too expensive to employ alone as an efficient insulating coat, and it is, therefore, applied as a single thin layer, supplemented by a layer or layers of compound rubber which consist of an admixture of pure rubber with certain other ingredients, such as french chalk, sulphur, naphtha (as a solvent), etc, with which, by a due series of apportioning the quality and nature of the resultant rubber compound is toned, so to speak, to the pitch required in practice. The resultant rubber, as may be expected, is in the form of a workable mass, not unlike thick putty in the majority of cases, and in this state is applied to the cable or wire in the form of strips.

Now, there are two methods of applying rubber strip to a cable. One, the slower and more expensive method, is by lapping it spirally, two adjacent layers being lapped in opposite directions in order to absorb the joint and render the coating homogeneous. The other method, and the one more generally adopted, is by longitudinal compression. Two strips of rubber are applied to the cable, one above and the other below, and are compressed together at the sides in the form of a seam, by their passage with the cable between a pair of hard steel rolls revolving in contact, and semicircularly grooved to the finished diameter of the covered cable. The seam thus made is an efficient one, and depends on a peculiar property possessed by rubber to a marked degree, viz., cohesion. If two freshly-cut rubber surfaces be brought into immediate contact, they will cohere and form as homogeneous a mass as the uncut remainder.

Mr. Terry in his article especially refers to the seam in rubber-covered cables, and, I think, rather inclines to regard it as a weak point, but if proper precautions be taken for the exclusion of dirt and moisture, and the covering rolls be accurately turned so as to form a complete circle, there is no danger of weakness.

The subsequent process consists in spirally lapping the cable with a strong canvas tape to resist expansion and its subsequent vulcanization by exposure to steam pressure at a stated temperature for a certain period. This latter process imparts elasticity and durability to the compound by a combination of sulphur, which is one of the ingredients.

By the judicious apportioning of the ingredients in the rubber compound, and by varying the thickness of the primary coating of pure rubber, the insulation resistance per mile of the finished cable is controlled, and in this manner any result from a few megohms to several thousand may be obtained. The subsequent results are, of course, slightly variable i.e., they do not resolve themselves into round figures, but an approximation to the required result is easily obtained by experiment. It is also possible to vary the subsequent insulation resistance by the degree of vulcanization, for the longer a rubber compound is vulcanized up to a certain point, the higher will be its immediate insulation resistance. Such treatment, however, beyond the recognized time limit is extremely injurious, as it shortens the "life" of the cable by artificially aging it; it is a trick resorted to nevertheless by unscrupulous manufacturers to bring their cables up to the specified insulation.

In the earlier days of rubber-insulated cables it was a recognized thing for engineers and others to specify high insulation resistances, and insist on having them, a custom which has, however, led to an investment in wisdom at the expense of the purchaser. With rubber, as with gutta-percha, it is not "initial meghoms per mile" which are required as much as durability, low electrostatic capacity, and resistance to disruptive discharge.

I have as yet touched but lightly upon the vulcanization process, which is based upon one of the most important properties of rubber, viz., that of combining chemically with sulphur when under steam pressure at temperatures varying from 250° to 350° F. The action is purely a chemical one, and the rubber, after the process, assumes an elasticity and durability which it did not possess in its raw mixed condition; moreover, the longitudinal seam due to manufacture, is rendered homogeneous by it, and is, in fact, difficult to localize after vulcanization. It is important to blend with the other ingredients just sufficient sulphur, and no more, than the rubber will take up, as, otherwise, a certain quantity of sulphur will be left free, and will, by its presence, tend to corrode the copper conductor. For this reason the latter is tinned, and in many cases what is known as a "separator" or layer of rubber with little or no sulphur in its constitution is introduced between the primary layer of pure, and the outer one of compound rubber, with the object of absorbing any excess of sulphur not taken up by the latter.

With a good quality, properly vulcanized, rubber-covered cable or wire one can do almost anything, short of willfully damaging the rubber coat. It will stand bending round its own diameter, and, indeed, very severe handling, before deleterious effects will be observed.

Gutta-percha, also an expensive material for insulating purposes, is not suitable for electric light and power work, where an appreciable rise of temperature in the metallic conductors themselves is at times unavoidable, owing to its susceptibility to variations of temperature. It is, however, admirably adapted for sub-marine telegraph cables, and also for telegraph and telephone wires laid underground. When new, it has a very light tint, but ages rapidly with exposure to air, darkening in color, owing to the formation of a crust of oxide on its outer surface, which becomes very brittle. The best conditions for its maintenance are to place it under water having a fairly even temperature of from 40° to 80° F. This prevents oxidation, and it will last under these conditions for years.

For underground work it is usually covered with a strong spiral canvas tape saturated with Stockholm tar, from which, however, the natural acids have previously been extracted. This latter is an important point. Such a covering has a similar preservative effect to the foregoing immersion in water, and it prevents ingress of air, and, in a moist atmosphere, at a fairly even temperature, answers very well.

The well-known Callender cables are insulated with a substance known as "bitite," which consists essentially of purified vulcanized bitumen. They are very suitable for low pressure town mains and feeders where they are not likely to be disturbed, and, for such purpose, are usually laid in troughs filled up solid with a bituminous compound. For general work, however, they will not stand the manipulation that rubber insulated cables are capable of withstanding.

Fibre cables, another substitute for rubber, are certainly cheaper, but they have many disadvantages, which, to a certain extent, annul any advantages due to a low prime cost. They consist mainly of a fibrous material, such as hemp, loosely wrapped round the conductor, and impregnated with suitable insulating compounds, such as bitumen, etc., and subsequently sheathed with lead to exclude moisture. Their disadvantages are numerous: in the first instance, fibrous materials are hygroscopic, and require to be well heated to expel any moisture which they may contain before being lead-sheathed. This heating tends to destroy the fibre. Then, again, air, although a splendid insulator when in a dry state, is unable to withstand disruptive discharges of electricity and it is practically impossible to manufacture a fibre cable and guarantee the insulating material absolutely free from air, as the latter is readily retained in the form of minute bubbles, which, when the cable is subjected to a high emf., speedily assert their existence by the breaking down of the insulation at that point. Finally, these cables absolutely depend for their insulating qualities on the total exclusion of moisture, and a pinhole in the lead sheathing, although not discernible under the initial tests, means the subsequent development of a fault. Pure lead also, if placed directly in the ground, is very subject to corrosion, although a slight alloy of tin decreases the risk in this respect.

To pass on to paper insulation. As far as telephone work is concerned, paper has evidently come to stay. As an insulating material it is light, cheap in prime cost, and—most important point of all—its specific inductive capacity is extremely low compared with other materials, all of which render it an admirable insulator for underground multiple wire telephone cables. Such cables have been largely adopted by the National Telephone Company, the paper being packed quite loosely around the wires in the lead sheathing, and, in conjunction with their system of passing a continuous current of dry air through the containing sheath, have proved highly satisfactory.

For electric light and power, paper insulated cables, as manufactured by the British Insulated Wire Company, of Prescot, for instance, are subject to the same disadvantages as fibre cables, but withal, are of comparatively low prime cost and are eminently suitable for low pressure mains and feeders, as well as with a greater thickness of dielectric for high pressures.

Summing up the various materials in vogue for cable insulation to-day, what is urgently required is a substance which, while possessing the durability, elasticity and imperviousness of rubber, shall be cheap, and yield good results electrically, i.e,, it must possess a low specific inductive capacity, and a high specific resistance, under all ordinary conditions, and above all, be capable of easy application to the wire or cable which it is intended to insulate.

Such a substance is not at present on the market, but a fortune awaits the lucky individual who discovers and patents such a compound.

Exports of Electrical Material from New York.

The following are the exports of electrical material and machinery, from the port of New York, for the week ended September 26:

Antwerp, 14 cases, $2,016; Australia, 47 pack-

ages, $4,517; 5 cases, $328; Berlin, 3 cases motors, $540; Brazil, 18 packages, $2,234; 539 packages electric railway supplies, $80,772; 43 cases, $5,557; Bremen, 16 cases,$2,043; 13 cases motors, $2,360; Bristol, 72 cases, $5,009; British Possessions in Africa, 156 packages, $11,001; British West Indies, 5 packages, $230; Bolton, 2 cases motor parts, $290; Central America, 1 case, $27; Chili, 13 cases, $348; 6 packages $200; Cuba, 14 cases, $181; Ecuador, 2 cases, $120; Glasgow, 27 cases, $4,661; 1 motor, $145; Hamburg, 129 cases, $13,634; Havre, 55 cases, $4,063; Lisbon, 69 cases $2,422; Liverpool, 135 packages, $12,694; 1 box, $20; London, 71 packages, $2,958; 72 cases, $2,800; Manchester, 5 cases, $406; Mexico, 1 case motor parts, $64; 547 packages, $12,026; Newcastle, 4 cases, $2,960; New Foundland, 4 packages, $85; Nova Scotia, 8 cases, $41; Oporto, 7 cases, $368; Peru, 22 cases, $1,193; Southampton, 48 cases, $5,649; St. Petersburg, 15 cases, 841; Trieste, 2] cases. $847; Venezuela, 241 packages. $1,545.

The following are the exports of electrical material and machinery from the port of New York for the week ended October 3:

Antwerp, 8 cases, $761; Argentine Republic, 218 packages, $8,747; 50 cases, $3,195; Barcelona, 14 cases, $840; Brazil, 67 packages, $2,818; 5 cases, $438; Bremen, 5 packages, $218; Bristol, 33 packages, $2,608; British West Indies, 30 cases, $943; British Possessions in Africa, 43 cases, $3,424; British East Indies, 1 case motors, $33; 26 cases $430; British Guiana, 2 cases, $73; Brussels, 15 cases, $327; Catania, 34 packages, $6,388; Cuba, 38 packages, $1,588; Danish West Indies, 1 package, $10; Dublin, 1 package, $185; French West Indies, 1 package cables, $14; Genoa, 2 cases automobiles, $1,000; 174 packages, $7,332; Glasgow, 381 packages motors, $4,582; 15 cases, $1,094; Hamburg, 10 packages, $2,154; 115 cases, $7,275; 2 packages trolley material, $250; Havre, 72 packages, $3,931; Hayti, 1 package, $50; Huddersfield, 13 packages, $304; Japan, 195 packages, $19,723; 73 cases, $9,384; Liverpool, 109 packages, $11,744; 1 case automobiles, $1,300; 6 cases, $190; London, 135 cases, $5,524; 72 trolley poles, $2,375; 25 packages motors, $481; 160 packages, $10,306; Manchester, 2 cases motors, $770; Marseilles, 2 cases, $180; Mexico, 18 cases, $3,806; Milan, 47 packages, $15,065; Naples, 99 cases, $6,865; Newcastle, 26 packages, $4,000, Peru, 18 packages, $537; Plymouth, 1 case, $6; Porto Rico, 1 case motors, $25; 27 packages, $446; Rotterdam, 28 packages, 228; Santo Domingo, 2 cases, $10; Southampton, 14 cases, $405; Stockholm, 1 package, $80; U. S. Colombia, 22 cases, $562; Venezuela, 2 packages, $38; Westeras, 1 package, $53; Zurich, 1 case, $49.

Dixon's Graphitoleo

The automobile is a self-propelled pleasure or business carriage. The three distinct types are the steam-carriage, the electric vehicle and the internal combustion engine. Each has its advantages and its disadvantages, but all three types are equally dependent on the proper working of the running parts.

Furthermore, in all three types it is especially desirable to waste as little power as possible, and to do this, the running parts must not only run properly, they must run smoothly and with the least amount of friction. For the best results, and for the greatest amount of pleasure to the occupants, the automobile must be treated as a machine—the same as the locomotive and the stationary engine.

The power transmission between engine and axle is usually by chain and sprocket, with a differential gear on the axle. To prevent rust and wear and to save power, all chains and gears should be lubricated with some form of graphite lubricant. It is graphite—Dixon's Pure Flake Graphite—that has proven most satisfactory for the chains of bicycles, and for all types of machines up to the mightiest steam locomotive that rushes along at more than a mile a minute.

Dixon's Pure Flake Graphite is prepared in various ways so as to make it suitable for the running and wearing parts of all the different types of automobiles. There is no substance that can equal it as a lubricant and it is generally used on all power machinery, large or small.

INCORPORATIONS.

The Mead Electric Company, Marion, Ind. Capital stock, $100,000. Directors: M. C. Mead, O H. Keller and Mary C. Mead.

The Pacific Electrical Works, Los Angeles, Cal. Capital stock, $250,000. Directors: Monroe Markham, G. L. Hardison, H. E. Carse, Los Angeles; L. W. Andrews, Ventura; Frank Taylor, Brookline, Mass.

The Washington Electric Supply & Mantel Company, Seattle, Wash. Capital stock, $10,000.

The Citizens' Electric Light & Power Company, Sandusky, O. Capital stock, $100,000. Incorporators: N. W. Dalton and J. F. Parkhurst.

The Olney Electric Light & Power Company, Olney, Ill. Capital stock, $28,000. Incorporators: Henry E. Hughes, Edward S. Hughes and William Bower.

The Aiglon Electric Company, New York City. Capital stock, $5,000. Directors: Jules E. Serre and Gustav Nordin, New York City, and H. R. Anderson, Rahway, N. J.

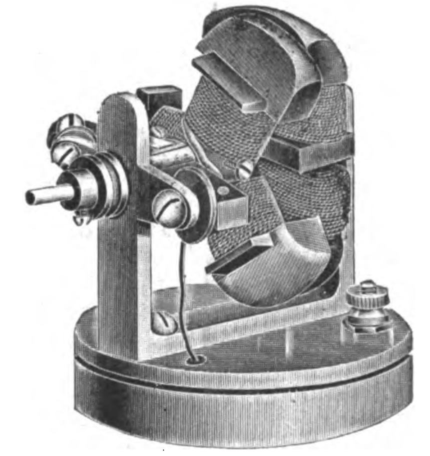
The Venice Electric Light & Power Company, Venice, Ill. Capital stock, $40,000. Incorporators: G. A. Nieman and F. Kohl.

The Versailles Electric Company, Versailles, Ky, Capital stock, $18,000. Incorporators: Edward Gunster, C. E. Stegmaier and John D. Farnham.

The Uniontown & Monongahela Valley Electric Railway Company, Uniontown, Pa.—to build and operate electric railways. Capital stock, $450,000. Incorporators: H. L. Robinson, W. C. McKean, I. E. Partridge, L. B. Hamilton, all of Uniontown; A. O. Lorentz of Meyersdale and J. S. Bryner of Scottdale.

COMMERCIAL PARAGRAPH.

The American Oddity Company, 170 and 172 West Broadway, New York, has recently placed on the market a novel motor—shown in the accompanying illustration—which has the advantage of requiring little power to operate it. The weight of this motor, which is known as "Oddo"



Junior, is but 11 ounces, and owing to the length of the arms of the armature (the magnetism going to the extreme ends) an unusal amount of power is derived through leverage, The "Oddo" Junior will run well on one dry cell and as the price postpaid is but $1, there should be a lively demand for this little piece of electrical mechanism.

COMING ELECTRICAL EVENTS.

American Street Railway Association—Will meet in Kansas City, Mo., Oct. 16-19, 1900.

Roentgen Society of the United States—Will meet in New York City Dec. 13-14, 1900.

ELECTRICAL PATENT RECORD.

[This department is edited by OSCAR A. MICHEL, Solicitor and Attorney for AMERICAN AND FOREIGN PATENTS, at 302 and 304 Broadway (Room 1204), New York City, also at 639 F street, N. W., Washington, D. C., who has been identified with this work before the U. S. Patent Office for more than fifteen years. Any inquiries upon the above subject as well as printed publications containing all information regarding the cost of United States and Foreign Patents, Trade Marks, Designs, etc., will be given free upon application by addressing OSCAR A. MICHEL, Nos. 302-304 Broadway, New York City, N. Y., or 639 F street, N. W., Washington, D. C. Copies of any patent published can be furnished upon payment of ten cents. When ordering give name, date and title of invention wanted.]

LETTERS PATENT ISSUED OCTOBER 2, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

658,854. Car-Fender. Henry Lutzenkirchen, Hartford, Conn., assignor of one half to Camillo L. Fischer, same place. Filed Feb. 14, 1900.

659,169. Mechanism for Supplying Electric Power to Railway-Cars. George F. Gale, Boston, Mass. Filed March 21, 1899.

659,178. Electric Railway System. Edmund C. Morgan, Chicago, Ill., assignor to the Morgan Electric Machine Company, same place. Filed Jan. 2, 1900. Renewed Sept. 10, 1900.

659,179. Combined Third and Traction Rail for Electric Railways. Edmund C. Morgan, Chicago, Ill., assignor to the Morgan Electric Machine Company, same place. Filed Jan. 2, 1900. Renewed Sept. 10, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

659,061. Electric Lamp. Frank L. Fowler, Philadelphia, Pa. Filed Oct. 26, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

658,821. Electric Generator. Leonidas G. Woolley, Kenton, O. Filed Dec. 28, 1899.

658,925. Electric Switch. Nathaniel D. Rand, Watertown, Mass. Filed Feb. 10, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

659,096. Combined Relay and Repeater for Telephone Lines. Edward C. Paramore, Philadelphia, Pa., assignor of one-half to Howard T. Goodwin, Ridley Park, Pa. Filed Nov. 18, 1899.

MISCELLANEOUS.

658,792. Circuit Making and Breaking Device. Paul M. Lincoln, Niagara Falls, N. Y. Filed Oct. 19, 1898.

658,808. Motor-Wheel for Automobiles. Herbert Simmons, Wellston, O. Filed April 3, 1900.

658,860. Cover for Battery-Jars. Philip P. Nungesser, Cleveland, O., assignor to the Nungesser Electric Battery Company, same place. Filed Feb. 18, 1900.

658,862. Telegraphone. Edward C. Paramore, Philadelphia, Pa., assignor of one-half to Howard T. Goodwin, Ridley Park, Pa. Filed Nov. 18, 1899.

658,865. Secondary Battery. Henry C. Porter, Chicago Ill., assignor to Owen H. Fay, same place. Filed Dec. 27, 1898.

658,891. Electrode and Electrode Connection. Henry Carmichael, Malden, Mass., assignor to S. D. Warren & Co., Boston, Mass. Filed May 11, 1899.

658,892. Canal-Boat Propulsion. Justus B. Entz, Philadelphia, Pa. Filed Feb. 10, 1900.

658,900. Battery Fluid. Gennaro Romanelli, New York City Filed Jan. 13, 1900.

658,905. Electric-Current Regulator. Daniel Watkins, Davenport, Ia., assignor of two-thirds to C. J. Ruymann, same place. Filed March 28, 1900.

658,924 Electrical Fitting. William T. Pringle, Lansdowne, Pa. Filed Feb. 12, 1900.

658,929. Electrical Semaphore System. Judson Shoecraft, Topeka, and Charles C. Gardiner, Bradford, Kan.; said Shoecraft assignor to said Gardiner. Filed June 20, 1899.

658,997. Electrical Propelling Apparatus. David Perret, Neufchatel, Switzerland. Filed June 20, 1890.

659,012. Automobile. Otto V. Bachelle, Chicago, Ill. Filed Oct. 2, 1899.

659,028. Phonograph. Barton B. Hill, Paris, France. Filed March 10, 1899.

659,080. Supporting Frame for Motors of Electric Carriages. Charles A. Lindstrom, Chicago, Ill., assignor, by direct and mesne assignments, to the Hewitt-Lindstrom Motor Company, same place. Filed May 5, 1899.

659,121. Appliance for Automobiles. Edward W. Ayres Washington, D. C. Filed June 16, 1900.

659,128. Steering Mechanism for Ships. Andrew B. Brown, Edinburgh, Scotland. Filed March 13, 1900.

659,142. Crossing for Suspended Electric Conductors. John Floyd, Washington, D. C. Filed Feb. 2, 1900.

DESIGNS.

33,303. Electric Switchboard. John Marion Creamer, Knoxville, Tenn. Filed July 23, 1900.

33,304-33,305. Lining for Switch-Caps. George B. Thomas, Hartford, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed Aug. 27, 1900. Term of patent 14 years.

THE TELEPHONE WORLD.

President Pro Tem. of American Bell Telephone Company.

Directors of the American Telephone & Telegraph and American Bell Telephone Companies have elected Alexander Cochrane president pro tem. succeeding John E. Hudson, deceased. Mr Cochrane is a director and member of the executive committee of both companies. The vacancy in the directorates, caused by the death of Mr. Hudson was not filled.

Articles of incorporation have been filed in Trenton, N. J., for a new telegraph, telephone, ticker and messenger service company to be known as the Exchange Telephone Company, with a capital stock of $5,000,000. The incorporators are Louis B. Dailey, Clifford Perkins, Evan J. Dudley, Charles A. Barkley, Kenneth McLaren, Horace S. Gould, Willard W. Baldwin, Thornton Parker, J. I. Billings and Adolphus Suedburg, Jr., James B. Vredenburgh, a Jersey City lawyer, who filed the papers, said that New York and Chicago capitalists are interested in the new concern but refused to make known their names or the plans of the company. The New Jersey Corporation Trust Company, with offices at 60 Grand street, will be the Exchange Telephone Company's New Jersey agent.

A syndicate headed by George R. Webb of Baltimore, Md., has bought out the Allegheny County Telephone Company of Pennsylvania. The company operates 850 'phones where the Carnegie works are located and at Braddock, a few miles outside of Pittsburg. These plants will be operated by interests friendly to the Pittsburg & Allegheny Telephone Company, which was financed by Baltimore capitalists. The Pittsburg & Allegheny Telephone Company has secured ordinances in Charleroi, California, East McKeesport, Swissvale and other points.

The Standard Telephone Company of Dubuque, Ia., began installing telephones recently. The company has four cables, each of 30 wires, and has laid cables in the alleys between several streets of that city. It has contracts with over 500 patrons for telephones and will put these in first. It expects to put in 1,200 to 1,500 'phones before a year. The rates will be $24 for a business house and $15 for a residence within a radius of one mile of the central station. Beyond that the charge will be increased in proportion to the distance.

The Bell Telephone Company is putting a free telephone in the office of City Clerk Hawken, of Kirkwood, Mo., and thereby hangs a tale of public enterprise pushed out in a new direction with success little hoped for by the pushers. The telephone is being put in at the request of the Kirkwook city council, on the theory that when a company puts a border of unsightly poles along the streets of a town, it ought to show the town some favors.

A short time ago the York, Pa., Telephone Company opened its lines into a new section of the county—to Lewisberry, Yocumtown, Newberrytown, Strinestown and Goldsboro. All of these connections are what is known as free 'phones to subscribers, or rather no additional toll is charged to reach those places. These new 'phones open a largely settled community to quick intercourse, which will not only be of infinite benefit to York but to those towns also.

Stockholders of the Isle of Wight, Va., Telegraph & Telephone Company, a local enterprise, met recently and elected Joseph W. Holloway, president, and J. W. Thomas, who was named as secretary and treasurer. The intention of extending the telephone lines to Waverly and ultimately to Petersburg was announced.

The Central District & Printing Telephone Company of Allegheny, Pa., will have to stand trial in criminal court on the charge of maintaining a nuisance in erecting telephone poles on the pavement of property owned by a citizen of that place.

A local company is being formed for the purpose of putting in an independent telephone line in Athol, Orange, Erving, Farley and Miller's Falls, Mass. It is the intention of the company to furnish telephones to subscribers for $1 per month.

Charles Morris, former proprietor of the Harrison Telephone Exchange, of Little Rock, Ark., has secured the franchise for an exchange to be established at Sapulpa, I. T., and will start construction work on his lines this month.

The Falls County Telephone Company is preparing to build another line from Marlin, Tex., to the bridge over the Brazos on the turnpike road.

The Pacific States Telephone Company made a net gain of 1,834 subscribers in September, the total number connected is 80,686, which includes 20,162 in San Francisco.

Pocket Telephone.

Evan Shelby, manager of the Lafayette, Ind., Telephone Company, has invented a pocket telephone for the use of police patrolmen in cities.

Mr. Shelby's plan is to place a number of small boxes on telephone poles in various parts of the city, equip each box with a battery and connect them with the central office. The boxes will be about 3 feet high, a foot in width and 8 or 10 inches deep, to admit a complete battery. In the bottom of the box, which is to be placed at convenient height on the pole, there will be a jack, into which a plug is inserted to make connection with the central office. Every policeman on the force will be supplied with his own pocket 'phone, which will enable him to hold communication with anybody in the city who has a telephone. The Shelby pocket telephone is small—not as large, and much lighter than a revolver—and can be conveniently carried in the officer's pocket. It is about 8 inches in length, and weighs less than seventeen ounces. On one end is a special transmitter, and on the other is a receiver. It is so made that when the receiver is properly placed to the ear, the transmitter is directly in front of the mouth. The receiver and transmitter are so constructed that they may be folded together when not in use, and can be adjusted to fit any head. An ordinary exchange plug is connected with the instrument and when inserted in the jack in the box, the connection with central is automatic, and the patrolman may call for any number he wants.

The Bell Telephone Company of Philadelphia has granted its stockholders the privilege of paying in three installments, on November 19, January 18 and March 18, for the new $1,000,000 issue of stock. The money subscribed, as well as the first $1,000,000, which makes the $2,000,000 authorized by the shareholders in March, will be used for betterments. The scheme is to provide a plant which will serve not only the 14,000 present subscribers, but 26,000 more, which the company expects to gain in the next few years. The company's gross receipts have materially increased over those of a year ago, but the net earnings, owing to expenditures, have been less than last. It is claimed that the company has been earning enough to pay the 8 per cent. dividend regularly.

W. H. McCulloch, of Vicksburg, Miss., of the Cumberland Telephone Company, recently returned from a business trip to Lake providence, La., where his company is arranging for a telephone exchange for that town also for a long distance service crossing the Mississippi at that point by cable, connecting with the long distance line to all points in the United States. A most desirable office has been secured at Lake Providence, and already the exchange has sixty five subscribers. Mr. McCulloch states that the service will be carried in an area of fifteen miles out of Lake Providence. He located the cable which will be about two miles in length, and hopes to have the entire service in operation in the next ninety days.

The Cumberland Valley Telephone Company has decided to build its line from Greencastle to State Line, Pa., where it will connect with the Hagerstown Company for through business. The Fulton and Franklin County line, which runs to Foltz, McConnellsburg, Welsh Run and Clear Springs, Md., has been purchased, which will put a stop to the negotiations pending between the Bell and the Franklin and Fulton Companies, and will give Mercersburg, Foltz and McConnellsburg exclusively to the Cumberland Valley line. The purchase of this new line will connect Welsh Run, Kaiserville, Clear Spring, in Maryland, and Waynecastle, State Line and Middleburg, in Pennsylvania.

The Inland Telephone Company will extend its service to the United States Marble Company's property, nine miles west of Valley, Wash. A switch system will be put in so that either the mill, boarding-house or quarry, which are about a quarter of a mile apart, can be reached from Spokane, Wash. The system is also so arranged that there will be communication between all parts of the property.

A new telephone system of modern pattern is being put in at the penitentiary at Columbus, O., by the board of managers. The wire will be copper with rubber insulation. A new keyboard of the latest design will be placed in the office of the deputy warden, which will be the "central office" of the penitentiary telephone system.

Franchises were lately granted the Chesapeake Telephone & Telegraph Company and the Newport News and Richmond Telephone & Telegraph Company to do business in Williamsburg, Va. A maximum rate of $38 on business 'phones and $30 on private 'phones is required. The companies have not yet accepted the franchises but in all probability will.

There is talk of a telephone line to connect Hamilton with Barnesville, Bexar, Detroit and Sulligent, Ala.

The Massachusetts Telephone & Telegraph Company will probably become an operating company by December 1. The company now has 175,000 feet of duct laid in the streets of Boston, and a contract will soon be let for 40,000 additional feet, making a total of 215,000 feet, or 43 miles of duct, which will be available for use by November 1. The number of ducts in the conduits vary from 4 to 72, the larger number being on Franklin street approaching the central station. Connections are now being made from the conduits to buildings. The company has from 5,000 to 6,000 subscribers under contract. The switchboard to be used in the central station has arrived from Chicago and is being installed.

The first telephone exchanges, according to a Kansas City, Mo., paper, were established in 1878, and by the next year the telephone was coming into general use. The census of 1880 showed 148 different companies, with 34,305 miles of wire and 54,319 instruments. During the twenty years that have elapsed the Bell interests have seen consolidated into the American Telephone & Telegraph Company, which controls 62-,000 miles of wire and rents twenty one times as many instruments as were in use in 1880. Nearly four million exchange connections are made daily. In 1876 it was a remarkable feat when oral "dispatches" were transmitted between Salem, Mass., and Boston. Now Kansas City may call up New York at any time and may even talk with Boston, 1,700 miles distant by wire.

The Citizens' Telephone Company of Racine, Wis., will shortly commence work on the new plant. Material is now on the way. There was some talk of the city enforcing the conditions of the first franchise of Allen Shewmon, but as it was shown that Mr. Shewmon did everything in his power to get the plant in the $1,000 forfeit will not be demanded and he will get the extension asked. There are over 200 stockholders in the company, all Racine men, and they have 500 subscribers just as soon as the 'phones are ready for use.

The Manhattan Railway Company of this city, will equip all its stations along the four elevated lines with telephones, which are to supplant in part the telegraph for official business. A report that the telegraph was to be entirely abandoned by this company was denied recently by the superintendent, who said that for some purposes the telegraph was indispensable.

The New York Telephone Company is making extensive improvements in Mount Vernon, N. Y. A $36,000 four-story fireproof exchange is being erected in South Fifth avenue, and ten miles of conduits are being laid through the principal streets, at a cost of about $10,000.

The Rawson Electric Company of Elyria, O., known as the Home Telephone Company, recently deposited a certified check with City Treasurer Harrington for $5,000, constituting a bond to begin the construction and operation of a telephone exchange in Lockport, N. Y. The franchise was granted last June.

On the night of October 3d wire thieves cut seventeen of the wires running through West street of this city, the only street in the city where the wires of the telephone company are stretched overhead. Some of the wires cut were those of the Fire Department, and others were long distance wires of the New York Telephone Company, running to Chicago.

The Long Distance 'Phone Company of Virginia will put up a line between Richmond and Petersburg.

TELEPHONE INCORPORATIONS.

The Exchange Telegraph Company, Jersey City, N. J.—to operate telegraph and telephone lines. Capital stock, $5,000,000. Incorporators: A. Suedburg, Jr., L. B. Dailey, C. W. Perkins, E. J. Dudley, C. A. Barkley, K. K McLaren, H. S. Gould, W. W. Baldwin, T. Parker, J. I. Billings.

The Oakville Telephone Exchange Company, Oakville, Ia. Capital stock, $5,000. Incorporators: E. I. Dunham, J. C. Thompson, D. A. Brown, A. L. Duncan, L. C. Edwards, E. B. Conkling and S. R. Gowthrop.

The Grant County Telephone Company, Silver City, N. M. Capital stock, $30,000. Incorporators. Patrick T. McGrath, Adolph Wisel, William D. Murray, Edward A. Blanton, Jr., Joseph W. Bible, all of Grant County.

The Hornellsville Telephone Company, Hornellsville, N. Y. —to operate a telephone line between Hornellsville, Olean, Bath, Wellsville, and intermediate villages. Capital stock, $50,000. Directors: Burt G. Hubbell, Cleveland, O.; F. D. Sherwood and James B. Day, Hornellsville.

The Central Indiana Telephone Company, Sheridan, Ind. Capital stock, $10,000. Directors: John H. Cox, Dorval Cox and Leland D. Cox.

GENERAL NEWS.

What is Going On in the Electrical World.

LIGHTING.

Ava, Ill.—R. J. Matthews is preparing to rebuild his electric light plant recently destroyed by fire.

Barnesville, O.—The arc lights lately erected are giving excellent satisfaction and there is now talk of increasing the number.

Batavia, N. Y.—George E. Crater, Jr., of New York will apply to the city council for a franchise for an electric lighting plant and electric railway.

Benton Harbor, Mich.—The city council is considering the question of erecting a municipal electric light plant.

Berlin, Wis.—The Berlin Electric Light Company lately decided to sell its plant in this city for $12,000. The system is to be remodeled.

Bronson, Mich.—Electrician Fredericks has purchased the outfit of the Bronson Electric Company and will take possession at once. He will begin the work of transforming it into an up to-date plant.

Carbondale, Ill.—This city contemplates the expenditure of $27,000 for the erection of an electric light plant.

Charleston, S. C.—W. I. Davids of the Charleston Hotel in this city invites bids for hotel electric lighting equipment.

Cumberland, Md.—The Baltimore & Ohio Railroad Company is arranging to establish a complete new electric light and power plant in this city, to light all the company's property.

Deerfield, Mich.—Deerfield's streets are to be lighted by electricity soon.

Denison, Tex.—Bids will be received by the American Cotton Spinning Company of this city for the installation of an electric light plant.

Devil's Lake, N. D.—This city will soon install an electric light system.

Fostoria, O.—This city may have another electric lighting plant soon. C. E. Palmer is at the head of a syndicate who want a franchise from the city council.

Galveston, Tex.—The city electric light plant wrecked by the recent hurricane will be rebuilt. D. Hall, superintendent can be addressed.

Hollins, Va.—The Hollins Institute will install an electric light plant for lighting its buildings and grounds.

Johnstown, O.—A movement has been started in this city to erect an electric light plant. Messrs. Swartz have asked for a franchise for lighting.

Kirkwood, Mo.—Bids will be received until October 16 for machinery, appliances and materials, and for the erection of an electric light plant. Address J. G. Hawken, city clerk.

Magnolia, Miss.—A stock company is about to be organized here for the erection of an electric light plant.

Marion, Va.—H. J. Palmer, of Washington, D. C.; A. J. Lincoln, O. C. Sprinkle, W. L. Dickerson, and others, of this place, have incorporated the Marion Light & Power Company, and will erect an electric light plant. The capital stock of the company is $10,000.

Montreal, Can.—This city is discussing the lighting of the city, as the present contract expires on December 31, 1903. A municipal electric light plant may be built.

Naperville, Ill.—Plans and specifications are being prepared for the erection of an addition to the electric light plant.

New Paltz, N. Y.—This village has voted to have the streets lighted again by electricity.

New York City.—Proposals for bids, or estimates for heating and ventilating apparatus and electric lighting plant, for new public school 122, will be received by the committee on buildings of the board of education at the hall of the board, southwest corner of Park avenue and 59th street, Monday, October 15.

Perry, La.—W. J. Davis is interested in the erection of an electric light plant in this city.

Philadelphia, Pa.—The Beck Company of 639 Spruce street, this city, intends to establish a combined ice and electric light plant in a town of about 5,000 inhabitants, and is desirous of securing a location in some Southern community.—The rumor of the sale of the plant of the Kingston Electric Company to a syndicate of this city has been confirmed through a reliable source.

Radford, Va.—The Electric Light & Power Company will make improvements which will cost $20,000. G. W. Miles is president of the concern.

Salem, Ore.—The Salem Light, Heat & Power Company was lately organized by F. R. Hanson, M. C. Anson and G. A. Rockwell for the purpose of operating an electric light and steam heating plant in this city.

Sea Isle City, N. J.—This city will erect an addition to its electric light plant. Thos. Ludlam, mayor.

Selin's Grove, Pa.—This place will vote on election day upon the question of increasing the debt of the borough for an electric light plant.

Spokane, Wash.—The Post Falls Electric Company will erect a plant to cost about $750,000. E. C. Riblet is making surveys and contracts will soon be let.

St. Edward, Neb.—This place is to have an electric light plant in operation in the near future.

STREET RAILWAYS.

Ann Arbor, Mich.—At a recent meeting of the council the ordinance committee submitted an ordinance granting a franchise to Messrs. Hawkes & Angus for the proposed electric railroad from Jackson to this city.

Auburn, N. Y.—It is thought the trolley line from this city to Skaneateles may be completed in four to six weeks.

Boulder, Col.—The scheme to build an electric railway from River Front Park to this city is being revived by J. Brisben Walker.

Clarksville, Ga.—W. S. Erwin and J. H. Hicks of this city are planning the construction of an electric railway between here and Nacoochee Valley taking in Porter Mills.

Durham, N. C.—A movement is on foot to connect this place and Chapel Hill by trolley. A company is to be organized to build the proposed electric line.

Fayetteville, W. Va.—A corps of civil engineers have been surveying the proposed route for the electric railroad from Fayette on the Chesapeake & Ohio Railroad to this city, the county seat, a distance of two miles. The road will be built at once by Baltimore capital.

Fonda, N. Y.—The Fonda, Johnstown & Gloversville Railroad Company has decided to equip all the cars of the electric division with Providence fenders, and orders are placed for a sufficient number to supply all the cars of the local and main lines.

Harrisburg, Pa.—A charter was lately granted in this city to the Apollo, Vandergrift & Leechburg Electric Railway Company, with a capital of $25,000. This company proposes to construct a trolley line four miles long from Apollo to Vandergrift.

Lafayette, Ind.—There is a probability that this city and Covington, or else Veedersburg, will be connected by an electric railway. A number of local capitalists have interested themselves and are pushing preliminaries.

Leesburg, Va.—C. C. Campbell, of Fairfax County, Va., and Mr. Henderson of Missouri, are the chief promotors of a company which has been organized with a capital stock of $300,000 for the construction of an electric railway from Washington west and northwest through Alexandria, Fairfax and Loudoun Counties. A power house to cost $60,000 will be erected on the farm of Mr. Campbell about eight miles west of Washington.

Lexington, Mich.—The Detroit, Lexington & Lake Huron Electric Railway Company has been granted a franchise by the township board for a road through this place to be completed by December 31, 1901.

Martinsville, Ind.—It was recently announced that work on the electric line to this place will begin November 1. The road will pass the main entrance to Bethany Park and through nine towns.

Monaca, Pa.—The borough council lately granted right-of-way for the electric line that is to connect this place with other Beaver Valley towns.

Oskaloosa, Ia.—Arrangements are being perfected between the mayor, members of the city council and those interested in the proposed company by which a new company is to be formed here for the purpose of building a street railway and operating an electric light plant. The officers of the company which will secure the franchise for the street railway and electric lighting system are W. M. Peatman, of Centerville, president, and C. Winter, of Oskaloosa, secretary.

Pontiac, Mich.—Geo. F. Fisher, president of the proposed Pontiac-Orion electric road, states that surveys have been completed, and that the road will be graded this fall and rails laid in the early spring.

Rochester, N. Y.—Promoters of the Ridge Road Electric Railway from this city to Buffalo say that they expect to be able to have the road in running shape in time to carry travelers to the Pan-American Exposition.

San Francisco, Cal.—Plans have been prepared by Superintendent Lynch of the Market Street Railway Company which will soon convert the cable railways into electric lines.

Toledo, O.—This city is to have another electric railroad tributary to intersect with the Traction Company's line.

MANUFACTURING.

Chicago, Ill.—The Chicago Electric Hose Company was lately formed here to manufacture hose and rubber goods and appliances on a capital of $200,000.—The Chicago Die & Electric Company was organized in this city for the purpose of manufacturing machinery, dies and electrical appliances with a capital of $5,000. Francis W. Maxstadt, Charles D. Cole and John Lyle Vette are all interested in the concern.

Knoxville, Tenn.—The Biddle Manufacturing Company of this city wants a 200 light, 110 volt dynamo, shafting, pulleys, 100 horse power boiler, 50 or 60 horse power automatic engine, etc.

New York City.—Philip Hartensfels and P. S. Homer of this city and W. R. Chipman of Jersey City are the directors of the Electro Purification Apparatus Company recently formed here to manufacture appliances for the purification of water and other liquids on a capital of $50,000.

COMPANY MATTERS.

Ashland, Ky.—The Ohio Valley Electric Company will expend in the neighborhood of $200,000 on improvements in this city. The power house here will furnish light for the cities of Ironton, O., Catlettsburg and Ashland, Ky., and Huntington, W. Va.

Brooklyn, N. Y.—With a view to improving the service, the Brooklyn Rapid Transit Company has reorganized its elevated railroad system into six divisions, instead of three, as heretofore. Each division will be under the control of a division superintendent, who will be responsible to General Superintendent Edwards.

POWER AND TRANSMISSION PLANTS.

Altoona, Pa.—City Engineer Linton of this city has secured right for water power at Loysburg, 25 miles south of here, to develop 6,000 horse power to be used for lighting and power and to operate a proposed electric railway from Hollidaysburg to Hopewell.

Brandon, Manitoba.—The Brandon Electric Light Company is now building a dam and will soon commence the erection of the power house and pole line.

Fort William, Ont.—E. B. Douglass, president of the Sault Ste. Marie Pulp & Paper Company, has planned a proposition to develop Kakabeka Falls, near this place, for electric light and power purposes.

MINES.

Denver, Col.—A Ball electric 10-light plant, with enclosed arc lamps of 2,000 candle-power, has been ordered for the Camp Bird mine. It will be used for lighting the grounds in the vicinity of the mine and mill. In all its phases the Camp Bird mine is probably the best equipped in the country and this addition to its electrical plant makes it virtually complete in every detail.

Montreal, Can.—The water committee has decided to call for tenders for the proposed electric motor plant for the high level reservoir. It is intended to have everything modern in this line of work. Canadian and American firms are expected to send in tenders, but the committee does not bind itself to accept the lowest or any of them. It will be arranged so that electric power may be obtained from any of the companies in Montreal.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16½@16⅝c.; Lake, 16⅝@16¾c.; casting, 16⅜@16½c.

A dividend of 2 per cent. has been declared on the United States Rubber preferred stock, payable October 31.

An interest in the new $30,000,000 National Telephone Company says that no steps toward more definite organization will be taken until after the election.

The Lowell, Lawrence & Haverhill (Mass.) Street Railway Company has petitioned the railroad commissioners for authority to consolidate with the Lowell & Suburban.

According to the Boston "News Bureau," arrangements are being made whereby the City of Chicago will light its streets by an electric plant owned by the city.

Earnings of the Chicago Union Traction Company for the last part of September show improvement over the first part; the increase for the month, it is stated, is over $5,400.

The Brooklyn Rapid Transit Company is considering a plan for the readjustment of bonds to gain the advantage of the premium on some of the issues. The profit to the company, should the plan succeed, would be in the neighborhood of $300,000.

At the meeting of the directors of the Chicago Union Traction Company on October 4, the old officers were re-elected. A dividend of 1½ per cent. was declared on the preferred stock, payable October 25. Books closed October 5 and reopen October 25.

The earnings of the Montreal Electric Street Railway, for the past year, show another substantial increase in income, the figures, as compared with the previous year, being for 1899: $1,646,647 and for 1900; $1,762,220, thus making the past twelve months by far the biggest year in the history of the company.

The active Lake Superior copper mining companies have about 14,000 shareholders, owning stock worth nearly $140,000,000, and which paid dividends in 1899 of $12,318,000. This gives an average investment of about $10,000 and an average income annually from copper dividends of about $900. Two-thirds of this stock is owned in Boston and its suburbs.

The Brockton (Mass.) Street Railway Company has filed a petition for authority to issue $400,000 bonds, also to purchase the West Roxbury & Roslindale, and the South Shore & Boston Street Railway Companies. The company also desires to issue $1,665,000 additional capital stock to exchange for the stock of the companies to be purchased.

The Metropolitan Street Railway Company of New York announces that it has finished all of the street work it will do this year. The company has spent about $5,590,000 for the most part on the power houses and motive power changes. Nine miles of Lexington avenue have been equipped for electric traction; six and a half miles of Columbus avenue have been electrically equipped; ten and a quarter miles of Broadway road have had new rails set, and the street surface repaved, and three crosstown lines have been reconstructed. President Vreeland says there is no intention of operating the present cable line by electricity until next spring, by which time he hopes to abolish the whole cable service on the Metropolitan lines.

The New England Electric Vehicle Transportation Company has had a very prosperous summer considering the small number of vehicles in operation. It has 100 cabs in operation in Boston and 50 delivery wagons and will probably not add to this equipment this winter. It has equipped its main station in Boston with apparatus for automatically charging the vehicles, which will effect a considerable saving in operating expenses.

The Metropolitan Street Railway Company of New York reports to the State Railroad Commission the general balance sheet of its system, as of June, 30, 1900, as follows: Third Avenue—Cost of road, etc., $25,165,505; stock of other companies, $9,636 497; bonds of other companies, $306,150; open accounts, $20,655,338; profit and loss deficiency, $282,309; total, $56,045,800. Liabilities—Capital stock, $15,995 800; funded debt, $40,000,000; real estate mortgage, $50,000; total, $56,045,800. Twenty-third Street—Dividends, 108,000; betterments, $362,424. Balance sheet—Assets—Cost of road, etc, $2,435,421. Liabilities—Capital, $600,000; funded debt, $400,000; due lessee company for additions and betterments, $874,356, bills payable, $500,000; profit and loss, surplus, $61,064. Forty-second Street and Grand Street Ferry—Dividends, 18 per cent., $134,640; rental under lease, $134,640; betterments, $500. Balance sheet—Assets—Cost of road, etc., $1,032,620. Liabilities—Capital, $748,000; funded debt, $236,000; Metropolitan Street Railway Company, $500; profit and loss surplus, $48,620. Dry Dock, East Broadway and Battery—Betterments, $4,575; gross earnings, $632,906; operating expenses, $459,809; other income, $6,036; fixed charges, $131,740; net income, $47,392; sundry charges, profit and loss, $15,335; total surplus June 30, $7,875. Broadway and Seventh Avenue—Rental under lease, $210,000; dividend 10 per cent., $210,000. Balance sheet—Assets—Cost of road etc., $13,332,775; open accounts, $52,500; total, $13,385,275. Liabilities—Capital stock, $2,100,050; funded, $9,650,000; dividend unpaid, $52,500; due lessee company for betterments and additions, $1,582,775. Bleecker Street and Fulton Ferry—Rent under lease, $13,500; dividend 1½ per cent., 13,500. Balance sheet—Assets—Cost of road etc., $1,801,931; bond extension account, $30,501; total $1,832,432. Liabilities—Capital, $900,000; funded debt, $700,000, Metropolitan Street Railway Company, $30,501; profit and loss surplus, $201,931. Central Park, North and East River—Betterments, $557,339; rental under lease, $162,000; dividend 9 per cent., $162,000. Balance sheet—Assets—Cost of road, etc., $4,048,863; profit and loss deficiency $189,132; total, $4,238,695. Liabilities—Capital, $1,800,000; funded debt, $1,200,000; due lessee company for betterments and additions, $1,238,695. Second Avenue—Betterments, $5,329,390; rental under lease, $148,960 dividends 8 per cent., $148,960. Balance sheet—Assets—Cost of road, etc., $8,194,413; profit and loss surplus, $77,686; total, $8,272,000. Liabilities—Capital stock $1,862,000; funded debt, $6,410,000.

ELECTRICITY.

Vol. XIX. NEW YORK, OCTOBER 17, 1900. No. 15.

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

Remit by Express, Money Order, Draft, Post Office Order or Registered Letter.

ADVERTISING RATES.

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter

EDITORIAL NOTES.

The American Street Railway Association Convention.

As we go to press the Nineteenth Annual Meeting of the American Street Railway Association is being called to order in Kansas City, Mo. Although the latter city is considerably further West than Chicago, where the Association met last year, it is expected that the attendance will be unusually large, and that the exhibits will be most attractive. There are certainly advantages in having the Convention held so far West, in that many small Western street railway companies will be offered an opportunity of being represented at the meeting, which would probably not be the case were the meeting held in the East.

As usual the papers to be read at the Nineteenth Annual Meeting are few in number, but on subjects that should prove of great interest to the street railway industry. The paper entitled the "Comparisons of the Various Systems of Electrical Distribution for Street Railways," should elicit an interesting discussion, as well as that on the "Consolidation of Street Railways and Its Effect Upon the Public."

The last day of the Convention, or October 19, will be given up entirely to an examination of the exhibits, which will embody the latest and most up-to-date appliances made use of on street cars or in connection with the street car service. On this same evening the annual banquet will be held when the officers-elect will be installed.

Judging from the number of well-known street railway men who have gone from this vicinity to the Convention it should prove a success. The proceedings of the meeting will be found in our next issue.

* * *

What is Being Done in the Line of Wireless Telegraphy.

There would seem to be considerable activity these days in the line of wireless telegraphy. The leading naval powers of the world are carefully keeping track of any improvements in the apparatus or method of transmitting signals, while only recently the British Admiralty is said to have ordered from the company, of which Marconi is the head, 30 complete sets for the use of the navy. The demand for wireless telegraphy apparatus on the ships of the English fleets, is due to the fact that during some recent naval manœuvres wireless messages were successfully transmitted 100 miles. For each installation of apparatus the British Government pays Marconi or his company $1,000, whereas a year or so ago he wanted $10,000 royalty, and $10,000 for each set of instruments installed on ships of the United States Navy.

It is understood that the Navy Department regards the rate of $1,000 as reasonable, and will make overtures to Marconi with the hope of securing a number of sets of instruments for use on the ships of this navy. Should an arrangement be effected the vessels of the North Atlantic squadron will be the first to receive the instruments. The experiments conducted in this country with Marconi's apparatus, as well as the excellent results obtained by the use of wireless apparatus on ships of the British Navy have convinced the Navy Department officials that wireless telegraphy would be of value to ships at sea.

Ever since wireless telegraphy was discovered to be practicable, Marconi has been endeavoring in every way to improve his apparatus and method of transmitting signals. He has been at work for some time devising a means of concentrating the waves that emanate from the transmitter, so that the receiver for which the message is intended, and that alone will be affected. His method of doing this has as yet not been entirely perfected, but will be in the near future, so it is understood. Another invention is that of transmitting messages over long distances without the use of the vertical wire, which has up to now been considered absolutely necessary. In a recent experiment Marconi succeeded in sending a message from Boulogne, France, to Dovercourt, England, a distance of sixty miles, by the use of a cylinder but four feet high, instead of the hundred foot vertical wire. This is on the belief, as expressed by M. Willot, chief inspector of the French telegraphs, that the messages leave the bottom and not the top of the poles, and that therefore the height of the vertical wires does not affect the distance a message can be sent.

As the Hertzian waves radiate from a transmitter, in much the same way that the waves of a quiet pond do when its surface is disturbed by the throwing in of a stone, it is rather difficult to see if, as has heretofore been generally believed, ether waves are responsible

Digitized by Google

for the transmission of a dispatch, how the curvature of the earth is to be overcome, and a wireless message recorded over a long distance, unless a vertical wire is used. Especially would this seem the case where a message is sent across a great expanse of water, as between ship and ship, where the water acts as a shield. However, if it is found that the vertical wires can be omitted and replaced by short cylinders, it will materially simplify the installation on board ship or elsewhere of wireless telegraphy apparatus.

* * *

A German Automobile Exhibit. American automobile manufacturers will be interested to learn that there has been organized in Berlin a permanent exhibition of automobiles, which will offer exceptional facilities for the motor vehicle builders of all countries to bring their products before the people of Germany under highly advantageous conditions, and at minimum cost. The association includes among its founders several prominent capitalists and business men of Berlin, its officers are men of the highest character and social position, and its purpose is not to make money, but to provide a permanent, legitimate basis of encouragement to the motor-vehicle industry in Germany, and to automobilism as an adjunct of sport, business and recreation. The managers of this enterprise realize fully that German manufacturers are as yet in some important respects behind those of France and the United States; they appreciate the advantage that will result from bringing the leading motor vehicles of all countries into practical, side-by-side competition, and they therefore offer to foreigners and their machines precisely the same privileges and conditions that are vouchsafed to those of their own country.

The association is a limited stock company, entitled "Die Automobil Ausstellung," with offices at No. 6 Dorotheen strasse, and exhibition grounds and driving school on Georgen strasse, Berlin. The space for permanent exhibits includes 1,200 square meters (12,902 square feet), with offices and all the features of a well arranged exposition. Floor space will be rented to exhibitors at a uniform half-yearly rate of $47.60 per square meter, with $14.28 per meter for wall space to be used for advertising purposes. This will be the only expense involved, no commission or other charge being made for vehicles sold when on exhibition or from samples there displayed. The space rates above stated will be reduced proportionately when the term exceeds six months. Vehicles and other articles on exhibition will be guarded by agents of the company, which will, when requested, effect fire insurance on exhibits at the expense of the owner.

It should be understood that the association is not commercial, and can not accept the business of selling, on commission or otherwise, the motor carriages or materials exhibited by any manufacturer, native or alien, but it will, when requested, recommend to foreign makers firms or individuals of good standing as agents in Germany, and its recommendation in this respect will be a high testimonial to the character and responsibility of the party recommended

An illustrated catalogue of all exhibits will be issued and corrected from time to time so as to include new articles received for display. The public will be admitted gratis to all parts of the exhibition, which will thus become a permanent, open, international business display of motor vehicles and parts and materials pertaining thereto, classified as follows: Motor cars of every description for conveying passengers; motor vehicles for the transport of goods; motor cycles and tenders for use with the same; accessories for motor-driven vehicles, fittings, tools, etc.; books on the subject, drawings, models, etc.; articles connected with the manufacturing, etc., of motor cars, etc.

That this permanent exhibition will meet an obvious want and exert an important influence in developing automobilism in Germany is beyond any reasonable doubt. There are today in Berlin and its outlying suburbs scores of persons—physicans, lawyers, and other professional and business men—who are ready and anxious to purchase an automobile, but not being mechanics or thoroughly informed on the subject, they distrust their own judgment and hesitate to buy lest they may find with experience that they have chosen unwisely and paid a high price for an inferior machine.

The permanent exhibition will give intending purchasers an opportunity to examine and compare side by side motor vehicles of all classes and nationalities, propelled by steam, hydro-carbon and electrical motors, to see them tested in competition with each other, and when a machine is chosen the buyer will be taught by an expert to understand and manage it. Numerous applications for space have already been received from French and Belgian makers, so that the exhibition will assume from the first an international character.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

THE National Electric Light Association has recently published a pamphlet of seventy-five pages, giving the results of experiments, which have been in progress for the last year at the Purdue University electrical laboratories at Lafayette, Ind. The object of this extensive research was to devise a method for determining the efficiency of the arc and incandescent lamps. The experiments by Purdue experts are of great interest to the public, for if they are successful it will be possible for the consumer to tell whether he is getting the amount of lighting power for which he contracts.

THE Free Public Library trustees of Newark, N. J., have granted to the Crocker-Wheeler Electric Company and the Watts-Campbell Engine Company a contract for installing in the new library building on Broad street a complete electric lighting plant. It is the intention of the trustees, if possible, to have the plant in working operation by December 1.

THE nominating committee of the Automobile Club of America announced the regular ticket October 10 which will come before the members for election at the annual meeting, Tuesday evening, October 23. The meeting will be held in the club rooms at the Waldorf-Astoria in this city, and early in November the club will take possession of its new rooms in the Astor Court Building. The officers nominated for the coming year are: President, Albert R Shattuck; first vice-president, Gen. George Moore Smith, second vice-president, J. Dunbar Wright; third vice-president, David Wolfe Bishop; treasurer, Winslow E. Buzby; secretary, Whitney Lyon; governors for the class of 1903, Albert C. Bostwick, Charles P. Doelger, and Dave H. Morris.

THE re-equipment of the electrical laboratories at McGill University at Montreal, Can., which was begun in the fall of 1898, following the munificent gift of Sir Wm. Macdonald, has been completed during the past summer. The dynamo laboratory, where the students carry on their experimental work, is divided into two sections, one for direct, the other for alternating current work, and is perfectly equipped with the latest types of electrical machinery. The machines are placed on raised platforms, and overhead travelers enable them to be placed wherever required. Switchboards are provided for current distribution, the electricity being obtained not only from the generating plant of the university, which is itself a veritable central station, but from outside electrical companies as well.

CONSUL HUGHES sends from Coburg some interesting facts about electricity on German farms. Near Ochsenfurt, in Bavaria, a company composed of landowners and small farmers has been organized for the establishment of an electrical system for use on their farms and in villages. The power is to be generated by steam and water and the current distributed from a central station to the places at which it is wanted. Sub-stations are to be established at given points, with the necessary apparatus for connecting with the farm or other machinery and also for lighting purposes in the houses, offices, roads and village streets.

NEWS from Virginia City, Nev., states that the machinery for the electric power to run the Comstock mines was tested recently and found to work perfectly. The mills will be run by electric power this week and a big celebration will commemorate the event.

THE new electric plant is in full operation at the Reward mine, in Nevada County, Cal. The mine has been pumped dry of water, sinking has been resumed in the shaft and two more pumps will be added to the mill.

A NEW light has recently been placed in the lighthouse at Pendeen, on the north west coast of Cornwall, England. The light gives four flashes in 15 seconds and has an intensity of 57,000 candle power.

THE first electric train of the Manhattan Elevated Railway Company is now at the company's shop. It consists of six handsome cars, a motor car being at either end of the train. The company has not announced yet when the trial will take place.

AN entirely new departure in the method of furnishing power to the mining companies, for the purpose of running hoists, pumps, drills and other mining machinery, will characterize the extensive power plant to be erected at Post Falls, Wash., by the new company which has been organized at Spokane. The power-house will contain dynamos capable of generating 12,000 horse-power, with four units of 3,000 horse-power each. Thirty thousand volts will be the pressure regularly maintained on the power line. An immense central plant will be installed at Gem, Idaho, which will generate

Digitized by Google

many thousand horse-power of compressed air. This compressed air will then be piped to the mines for the purpose of running their machinery, and, besides being a new feature in furnishing power, it will also institute a great reduction in the cost of operating.

The E. P. Allis Company of Milwaukee, Wis., has recently closed a contract with the Government of New South Wales, Australia, for three engines for generating electrical energy for traction purposes, to be erected in the power-house of the electric tramway at Sydney. These engines are to be of the vertical direct coupled pattern similar in design to those erected in the power house of the Milwaukee Street Railway and in the power house of the Metropolitan Company of this city.

There is about to be constructed at Budapest, Hungary, at the expense of the Government, a telephone exchange. This station will have a capacity of 10,000 subscribers at first, and will be so designed as to enable it at some future date to care for 20,000 subscribers. Firms of any nationality may submit bids for the work.

The idea of combining an ordinary home exerciser with an electric machine, so that the stimulating effect of electricity is obtained in combination with the muscular exercise, has recently been conceived by a company in Wisconsin. In appearance the machine resembles the ordinary exerciser with elastic cords passing over pulleys. But the cords serve as conductors, and the handles as electrodes. Somewhat below the middle of the board on which the pulleys are fastened, a cell is placed, and wired to an induction coil, secured to the upper part of the board. The induced current is conducted through the elastic cords, to the handle and back again. A metallic foot plate, furnished with the apparatus, can be placed in the circuit, so that the current may be passed completely through the body, if desired.

The pressing necessity for the reorganization of the army on modern lines is pointed out in the annual report of Major General John R. Brooke. Among other things Gen. Brooke commends the system of wireless telegraphy established by the signal service, and says that plans should be perfected immediately for complete and perfect communication between the units composing each fortress and the fortress commander.

Clarence W. Dolan lately returned to Newport, R. I., to make a test of a new electric automobile that he has had made for touring purposes. It is constructed both for speed and endurance, and is long and narrow, so as to offer as little resistance to the atmosphere as possible. It will run 120 miles without being recharged, and is designed for an average speed of twenty-five miles an hour.

G. A. Wiese, of Alameda, Cal., who went to China some years ago to install an electric light system for the city of Canton, had some interesting experiences with the Chinese. "In many places," he says, "the streets of Canton were too narrow for poles. We had to get permission of the authorities to cut holes in the walls of the buildings. Into these holes modern cross-arms were inserted. After the cross-arms had been placed and the wires strung we made a tour of inspection and were astonished to find that the wires were loaded with laundry work that had been hung out to dry. A current of 1,000 volts was running through the wires at the time, but luckily no one had been killed. When the Chinese were warned of their danger they only laughed and said that the electricity dried their clothes much quicker than the sun, so they refused to move their wash. Mr. Wiese finally had to report the matter to the authorities, who detailed a guard of 40 soldiers to go with him and put an end to the clothes-drying.

That business gentlemen in England should, on using a telephone and finding that they have been put on to the wrong number or switched off suddenly in the middle of a conversation, protest in a very vigorous fashion, is now a standard joke, says the London "Electrical Engineer," but the anger exhibited does not usually go farther than words. The hasty temper of the Spanish race is proverbial, but one would not think that any man, however angry, would do deadly injury to a telephone instrument. This, says our contemporary, is what occurred recently in Paris, when a Spaniard, who had been switched through by telephone from his hotel in Paris to a stranger instead of a friend, lost his temper and fired four shots into the instrument, entirely wrecking it. Naturally he had to pay heavily for repairs and also to leave the hotel.

The early development of the lignite coal fields has been promised the people of North Dakota at Wilton, the first station on the line of the Bismarck, Washburn and Great Falls Railway. An equipment consisting of a steam engine and an electric plant has been bought by the railroad company and the new machinery will be installed in the mines. The principal advantage in the new apparatus is the increased capacity of the mines which its use makes possible. Two electric cutters, machines for sawing the coal out of its beds, will be put in operation as soon as the machinery is set up. These two cutters will enable the operators to mine about 400 tons of coal per day. The machinery has power sufficient to drive six of the cutters, and as the company is away behind in orders, the satisfactory installation of the plant is the only thing necessary to run the electric devices to their full capacity.

I. N. Bettison, superintendent of the city water works of Brenham, Tex., has invented a device, and applied for a patent, intended for use on railway engines provided with electric lights. As constructed at present these lights are not adjusted to curves, and on a piece of crooked track the light falls either to the right or left of the rails. Mr. Bettison's device is arranged so that the engineer by a simple movement of the hand can make the light follow the rails, regardless of curves.

C. W. Price of the Montauk Multiphase Cable Company, who has been ill for the past seven months, is now quite recovered, and can be seen at the office of the company, 100 Broadway, New York.

An installation of electric traction has been made by the Société de Traction Electrique su Voies Navigables along a distance of about 47 miles, from Béthune to L'Escaut, in France. The boats to be drawn carry from 270 to 300 tons, and draw about 5 feet of water. The piece of canal fitted has six locks. The cost of steam traction or animal haulage, says the "Electrical Engineer," London, is .427d. per kilometric ton; for electrical haulage this is reduced to .285d. The actual length of canal fitted for electricity is about 16 miles, and this is effected by two stations about 6¼ miles distant from each other, and having installed a total power of 400 hp. Continuous current at 500 volts is produced by eight generators. Overhead wires are hung on posts about 44 yards distant from each other at a heigth of 21½ feet above the towpath. The tractive apparatus consists of about 30 electrical haulers, each weighing two tons and mounted upon four wheels, of which only two are driven. The length of the haulers is about 14 feet, the breadth being about 4½ feet. The electric hauler can easily draw two 300-ton barges at a speed of nearly two miles per hour.

The "Elektrotechnisher Anzeiger" thinks one outcome of the progressive improvement of accumulators will be that electrically propelled boats designed to accommodate from 100 to 150 passengers will prove dangerous competitors of steam-driven boats. The insignificant attendance required, involving no stoking, absence of smoke, and the possibility of attaining very high speeds, are all points in favor of their extensive introduction. At the same time, it must be remembered, that the wear and tear of accumulators employed for boat propulsion is much less than in the case of road traction, since the concussions so detrimental to the life of the plates is almost entirely absent. It is also to be anticipated, considers our contemporary, that one will depart in the future from the principle of providing services of large steamers at long intervals—because small steam-engines work less economically—in favor of running small boats at short intervals.

The "Union" presses of Port Jrevis, N. Y., are now running by electric power. The motor is of 12-horse-power, and gives double the power it really needs. Heretofore the power (water) has been insufficient to run all the presses at one time, but this new motor sends every machine, which includes two very large presses, two smaller ones, and a large folder with all the speed desired, and all at the same time.

A telegraph line has been completed between Seattle, Wash., and Skagway, Alaska, and put into operation. The route is from Skagway to Atlin, thence over the old Atlin-Lillowit line to the Fraser River, thence to Ashcroft and on to Vancouver, from which place it runs to Seattle. The line between Skagway and Vancouver is that which the Canadian Government has been engaged in constructing for the past four months.

Bids have lately been asked of several leading electrical engineering firms for equipping an extensive electric power-supply plant in the Mysore (India) gold mining district. Current is to be generated at the Convery Falls and conveyed 100 miles to the gold mines. The Mysore Government is to defray the cost of the installation.

SHOULD THE USE OF GROUND WIRES IN CONNECTION WITH FIRE ALARM TELEGRAPH BE DISCONTINUED?*

BY MORRIS W. MEAD.

I have been unable to get time enough to prepare a lengthy paper upon the subject assigned, on account of the Annual Convention of the International Association of Municipal Electricians' meeting this year in my own city of Pittsburg, and being one of its officers, a large portion of the work has fallen upon myself to carry through. This, I feel, will be sufficient excuse for the short and summary way of presenting my thoughts upon the subject.

The paper which I have the honor to present to this convention, it seems to me, is of considerable importance to those having charge of municipal telegraphs, that is fire and police signal systems, upon the security and the reliable operation of which so very much depends, and any suggestion or discussion that will in any way tend to maintain the integrity of such service is, I am sure, of very great interest.

We all know how very undesirable it is to have grounds, or escapes, leakages of any kind occurring to fire and police telegraph circuits and the liability to troubles always existing from these sources, and any improvements or methods that will tend to avoid these indicated troubles, certainly help to remove a portion of that constant anxiety always in the minds of the parties in charge.

One of the important questions in my mind refers to the matter of maintaining permanent ground connection in police and fire alarm signal boxes, and whether or not it is desirable to have such boxes permanently connected with the ground, as has been the general custom.

Before the advent of heavy currents, such as electric light and trolley currents, there was no objections to a good ground connection permanently maintained at all signal box points of the kind indicated, but since the development of electrical currents of high voltage or in large quantities, it is certainly a very different matter, and I have come to the conclusion that it is safer to fire and police systems to be without a permanent ground connection at such points.

Of course we all understand the convenience that a ground connection furnishes when testing a fire or police signal system or when an "open" occurs, and I do not mean to convey the idea that ground wires are not desirable under certain conditions, but while I recommend having a good ground wire connection at all box points, I also believe it is not desirable to connect this wire permanently but instead to have it so arranged that it may be conveniently connected to the circuits when it is necessary to do so for any purpose.

One of the principal uses of a permanent ground connection at all signal boxes was to protect the box from lightning discharges, but the system now in general vogue of having fuse protection on all circuits, and grounded bars or plates at headquarters, it seems to me furnishes satisfactory protection in that particular respect, and therefore a ground wire lightning arrester is not really necessary to protect the system at such points, as was the case in former times when fuses were not so generally used as now.

Investigation on my part has led me to believe that very serious trouble has very frequently been introduced into fire and police telegraph circuits because of ground wires permanently connected at box points, and the trouble introduced into the system because of leakages from trolley or other heavy current, or escapes existing in water or gas mains and in that way brought into the system, which have caused very serious harm.

I have been told upon several occasions fire-alarm circuits have been found supplied with considerable current in that way although entirely disconnected from the battery operating such circuits, and undoubtedly this outside current has been brought into the circuits through the ground connection at the box points. This illustrates only one of the dangers occurring from such methods of construction. Another serious harm likely to ensue from these permanent ground connections is caused by heavy current wires coming in contact with wire and police wires, and owing to faulty causes at the ground plate in the signal box grounds or partial grounds have been left and serious burn-outs have occurred on that account to the system in use in such places. It is quite difficult to keep the spark-gap space thoroughly well insulated between the ground plate and the main line terminals on the lightning arrester used, and in that way frequently harm has been caused.

I understand that quite a number of fire-alarm superintendents have given this matter very careful consideration, and have very much improved the security of their respective systems in adopting the plan suggested herein, and that since this plan has been used troubles that heretofore were of frequent occurrence have been entirely removed.

*Paper presented at the Convention of Fire Chiefs, Charleston, S. C., Oct. 9-11, 1900.

ADDITIONAL NIAGARA POWER.

BY FRANK C. PERKINS.

Preparations are rapidly being made by the Niagara Falls Power Company to supply additional power for use at the Pan-American Exposition at Buffalo next year. The excavations and masonry for the new machinery is well under way as will be noted by the illustrations, Figs. 1 and 2, the first showing the new wheel pit from the transformer house, and the second showing the same looking towards the power house, already working to its full capacity. The interior of the power house with its full equipment is illustrated in Fig. 3. There are now in operation at the present power house ten generators of 5,000 horse power each, supplying a two-phase current at 2,200 volts and transformed, either by rotary transformers to a direct current for railway purposes in and about Niagara Falls, or raised at the transformer house to 11,000 volts and transmitted to Tonawanda and Buffalo for lighting and power purposes. A large amount of the power is used at the Falls on the lands of the Power Company for electro-chemical purposes, and this is what has consumed most of the available power and necessitated the enlargement of the plant.

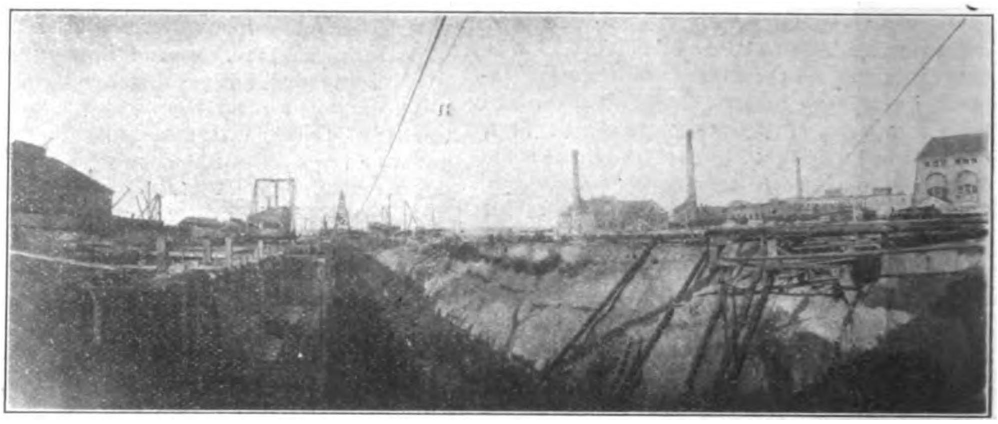

FIG 1.—NEW WHEEL PIT OF NIAGARA FALLS POWER PLANT, VIEW FROM TRANSFORMER HOUSE

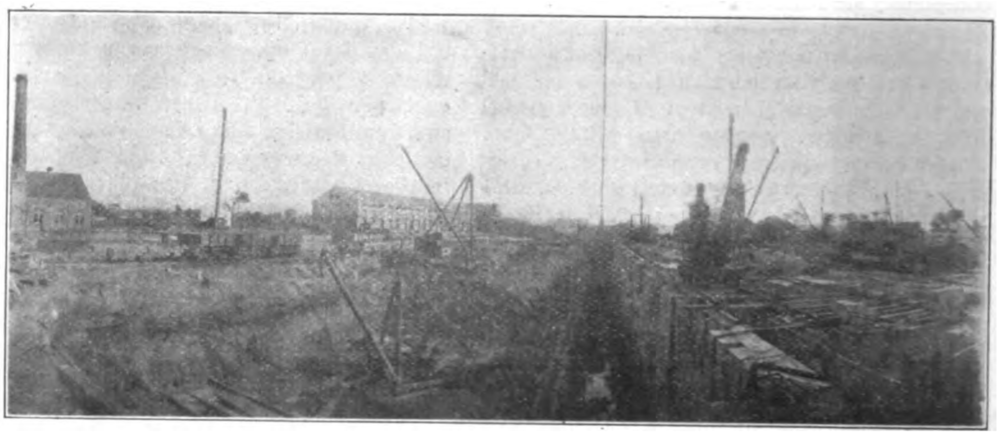

FIG 2.—NEW WHEEL PIT OF NIAGARA FALLS POWER PLANT, SHOWING POWER HOUSE AT THE LEFT.

At the Pan-American Exposition about 5,000 horse power will be needed from the Niagara plant which it is now preparing to supply.

Nineteen transformers of the General Electric air blast type will be used in the Electricity Building for reducing the pressure of the polyphase current from 11,000 volts to 2,000 volts and small step-down converters will be utilized in pits about the grounds and in the various buildings for again reducing the potential from 2,000 volts to 104 volts for use in light-

ing and power work. For the first time in the history of exposition decorative lighting incandescent lights of 4, 8 and 16 cp. will be used exclusively from an alternating current of as low a frequency as 25 cycles per second, as generated at the Niagara power house.

Several hundred men are now engaged on the new wheel pit which has nearly reached 100 feet in depth. The wheel pit is nearly 500 feet long, and in it will be installed a total of 55,000 horse power in 11 units of 5,000 horse power each. Half of the generators and turbines will be installed at once, making 30,000 horse power of available electrical energy during the coming year, and a total of about 80,000 horse power. An underground passage will connect the new wheel pit with the old one more than 100 feet from the surface.

The work on the new wheel pit is being pushed forward very rapidly both night and day, and besides the arc lights a powerful searchlight is used to aid in the illumination of the wheel pit. The various cranes, towers and cableways used in the construction work are seen in Figs. 1 and 2.

The European visit of the engineers, Brackenridge and Sellers, has resulted in some changes in the present installation to bring the new work to a more perfect state, and it is said the new turbines will be constructed according to the latest designs. It is the intention to have the new plant in operation by June, 1901.

ALUMINUM is being used for feed wires in the extensions of the Cleveland, Elyria & Western trolley system in Ohio.

FIG. 3.—5,000 HP. GENERATORS INSTALLED IN THE NIAGARA FALLS POWER COMPANY'S PLANT, NIAGARA FALLS, N. Y.

AUTOMATIC FIRE-ALARM SYSTEMS.*

BY CHARLES BURGHER,

Boston, Mass.

Before proceeding with the subject in hand I desire to thank you for your kind invitation to read before you a paper on the subject of "Automatic Fire-Alarm Systems."

When I received your invitation through your president I doubted my ability to do justice to the subject; and, allow me to say, that doubt has only become stronger.

I trust I may be able, however, to present some matter which may be of interest to you.

Description.—Briefly described, an automatic fire-alarm system consists of thermostats, or heat detectors, placed on the ceiling throughout the premises to be protected, twelve to fifteen feet apart on an open floor, and in every nook, closet and corner of the building.

These are connected by electric conductors to a signal-box placed in an accessible part of the premises, and this box in turn is connected electrically to a central station—if in a central station system—or to the nearest fire department quarters and engineer's or proprietor's house if in an isolated plant equipment.

These thermostats are usually adjusted to operate at a temperature of forty (40) degrees Fahrenheit, above the maximum temperature of the premises.

As soon as this predetermined temperature has been reached, the operation of the thermostat, either by completing or making a circuit, or by breaking one or more circuits, causes the signal-box or transmitter, by the operation of electro-magnets contained in said box, to become operative, which records at the receiving station by make or break signal wheels, certain numbers of long dashes, usually on "Morse" recording registers, designating the house or building number, and shorter dashes or records which denote the particular floor or section of the premises, each building or property having a specified box number.

In an isolated plant system this box number is transmitted directly to the nearest fire department quarters. In a central station equipment these signals have to be repeated to the nearest fire and protective department companies, in some cases by direct wires from a central station to the departments referred to; in other cities a system or form of repeating through the city fire-alarm headquarters is employed.

In some particular fire-alarm systems, however, the floor or section number is made known to the fire department when they arrive at the premises by means of an annunciator placed on the outside of the building.

In all systems this form of annunciator signals may be used in addition to, and operate simultaneously with, the fire department signals, to notify or alarm the occupants of a building, warning them that a fire or dangerous heat has been generated in a particular portion of the premises.

In connection with automatic fire-alarm equipments there are also placed in various parts of the building locked boxes with glass fronts for breakage and consequent working of the system, should fire at any time be discovered before it had generated sufficient heat to operate the system automatically.

Thermostats.—Thermostats form an important part of a fire-alarm system, and in view of the large number of thermostats now in general use, it may be of interest to trace their development in this connection.

First.—Probably the first practical thermostat constructed, certainly the first one to be put into general use, was through the application of the principle of expansion of metals.

This instrument was developed from a patent taken out in 1863 by Alexander Ross of Brooklyn, N. Y., for "Improvement in fire-alarm and heat detectors," and a modified form of the "Ross" patent served as a model in developing the first practical instrument.

The improved thermostat, patented in 1873, consisted of a compound spring of metals, in a coiled form, one end attached to insulating material and enclosed within a metal tube or cylinder. A pointed screw is placed through this cylinder directly over the free end of spring, and adjusted at any distance from same. A rise in temperature to a predetermined degree would cause the free end of spring to move by expansion and come in contact with the screw point, thereby closing an electric circuit.

This instrument is still in very general use, although experience has shown the desirability of placing the spring in a manner better suited to the conditions of the apparatus with which it is electrically connected.

Since the introduction of the above-described instrument other forms have been devised in which the same principle of expansion of metal has been employed. Among these, and the one in use to some extent, has the metals in the form of a disk, secured at its periphery, the

* Abstract of Paper read at the Fifth Annual Meeting of the International Association of Municipal Electricians, held at Pittsburg, Pa., Sept. 25-27, 1900.

Digitized by Google

movement from expansion being obtained by the concaving of the disk.

Among other principles employed in the construction of thermostats, are those employing mercury, volatile fluids, and fusible solder. Various forms of each of these have been devised, but space will only permit me to give a brief description of the forms which have been more generally used.

Second—Those in which mercury is employed consist of a glass or metal receptacle in which the mercury is placed, in some resembling a thermometer tube, in others, a small metal cylinder. At a predetermined point above the mercury is placed metallic points of an electric circuit. An increase of temperature to this predetermined degree causes the mercury to rise and to complete the circuit.

Third—Volatile fluids are generally employed by confining these either in a small round tank, one end or one side of which is flexible, or in a small flexible metal tube in circular form, secured at one end. The application of heat to these instruments causes the fluids to be changed into gases and through these gases being confined, the flexible end of the metal tank convexes, in the first case, and in the other, the flexible tube straightens out, these movements causing electric circuits to be completed or broken.

Fourth—Of the many thermostats arranged in which fusible alloy is used, a simple form consists of a small metal ring to which is attached by fusible solder, at diametrical points, two copper tubes, with holes in tubing just large enough to admit a suitable connecting wire, allowing an electric circuit to be completed through the whole arrangement, its operation by heat depending upon the solder fusing and breaking the circuit.

Fifth.—Another more elaborate arrangement is constructed in which compression of air takes the place of electricity in, primarily, recording its operation. In this instrument a strong spiral spring of steel is held in position under pressure within an air cylinder by a peculiar and suitable fusible solder joint. To the end of spring which is held depressed is attached an asbestos washer, made to fit closely in the cylinder by the use of paraffin and wax. In case of a temperature sufficient to fuse the solder at joint, the contracted spring is released, and by suddenly forcing the washer to the other end of the cylinder, the air is compressed through a series of pipes with which the thermostats are connected, causing an alarm to be sounded.

It is of interest to note that of the various forms of thermostats now in general use, all, so far as it has been the writer's privilege to learn, employ as a basis one of four well-known principles, namely, differential expansion of metals, mercury, volatile fluids or fusible solder.

Transmitting Apparatus.—Various forms of signal boxes, or transmitters, are employed to transmit an alarm from a protected building to the fire departments or central station, upon the operation of the thermostat; but as most of those in general use at this time are of the make or break wheel pattern, they are too well known to need any special description; all of these operating by a simple train of wheels, causing circuits to be completed through a series of springs coming in contact with cogged wheels, the wheels containing a predetermined number of cogs, long cogs denoting the house or building number, and shorter cogs designating a particular floor or section of building.

It is of interest, however, to note a particular recent invention in this direction, in which the alarm is transmitted by the human voice, by means of a phonograph attachment. The operation of the thermostat in this case causes a mechanism to become active, sounding a warning alarm at the receiving station of the fire alarm company, and then, by automatically connecting a phonograph cylinder direct to the circuit, the operator at the station hears, in a loud voice, by means of a graphophone apparatus and megaphone attachment, the necessary instructions pertaining to the fire alarm. For instance, he may hear "There is a fire on the second floor of 26 Broad street," this being repeated a great number of times.

Wiring.—A feature of special value in automatic fire alarm protection is found in the system of wiring employed in improved fire alarm systems. This consists of a duplex system of wiring whereby a broken circuit, a grounded circuit or a short circuit, will not impair the efficiency of the service: this being accomplished by means of a ground connection or "Morse" circuit connected with a metallic circuit of wiring, with both a "break" wheel and a "make" wheel in the signal box.

This furnishes an extremely valuable system, for, should the circuit become grounded, an alarm may be received by means of the break wheel on the metallic circuit. Should the circuit be broken, the alarm will be given on the opposite arm of the circuit by means of the "Morse" or grounded connection; while, should the system be short circuited or crossed, the alarm will respond by this same ground connection, the two arms or sides of the circuit acting as one conductor.

I may be excused if I incidentally express, at this time, my surprise that such a system has never been generally adopted in case of municipal fire-alarm circuits, where one "break," on a metallic system which is usually employed, renders the whole circuit inoperative.

Central Station.—The central station of an automatic fire-alarm system so closely resembles a municipal fire-alarm station, or headquarters, that a special description at this time might seem unnecessary. Here are maintained, night and day, a force of operators and inspectors, ready at all times to transmit, or repeat, automatic alarms to the fire and insurance departments, and to otherwise look after the apparatus in their charge.

As I have already stated, in some cases these alarms are repeated to the departments by means of direct wires leading from the automatic alarm station to the individual companies of the departments; two or three companies, usually, being assigned to respond to these alarms.

It will be understood that these signals denote to the departments the precise location where fire, or a dangerous degree of temperature has been generated. The particular floor, or location within the premises being made known by adding to the house or property signals, shorter or quicker blows. For instance, house signal 234 followed by four quicker strokes on bell may designate to the departments that there is a fire on the fourth floor of building No. 260 Church street.

In other forms of fire department connections these automatic signals are repeated to the city fire-alarm headquarters, and from there transmitted to the department companies over the regular municipal circuits, these alarms being preceded by a special signal number which denotes that the signals to follow are for an automatic alarm, the departments having, of course, a schedule of all automatic signals, somewhat similar in form to the regular fire-alarm running card.

In isolated plant systems—so called, which service is almost entirely confined to small cities and towns, the local fire company, or perhaps a proprietor's or engineer's dwelling, or both, is substituted for or made to act as a central station.

While very efficient service may be obtained from such equipments by close observance of rigid rules issued by the insurance people relative to such installations, yet, the particular benefits derived from central station service, such as constant care and oversight by competent employes, is lacking in this form of connection.

Merit and Value.—The merit and value of automatic fire alarm protection can hardly be overestimated. I am speaking now of a system which is practical in its construction: a system in which due care has been exercised in arranging its several parts in a manner suited to the numerous conditions met with in different classes of property to be protected; a system over which the care and supervision has been placed in proper hands in the hands of one who realizes that simplicity in arrangement, durability and excellence in construction, and frequency and faithfulness in inspection are absolute essentials in an efficient system of automatic fire-alarm.

In such a system there is almost absolute certainty that any rise in temperature to a point of danger, at any hour of the day or night, will instantly be communicated to the proper parties, and the firemen advised by such signals—not only of the particular building or property, but also of the exact floor or section location—start out with perfect knowledge of the precise point to attack, and with the assurance that they have but a small fire to contend with, if it is promptly reached.

Such is the service rendered by automatic fire-alarm systems, and if this result is not attained in some forms of apparatus it is probably because all the requirements of the service expected and demanded have not been fully understood or provided for.

The merit and value of automatic fire-alarm systems might be submitted in the simple statement that "The first five minutes of a fire is worth five hours." Upon this principle is based the faith of the introducers of this form of protection. The users of this apparatus realize also that "fires must be discovered before they can be extinguished;" and this basic principle applied toward the prevention of large fire losses will continue to attract the attention of property owners and agents, insurance people and the public generally, until the installation of automatic fire-alarm systems becomes almost universal.

The generally accepted value placed on automatic fire-alarm systems is that they prevent large fire losses by the discovery of fire in its incipiency. Their value extends far beyond this, however; and I make the assertion that, could the real facts be known, it would, undoubtedly, be shown that, for every million dollars' worth of property saved from loss by fire by means of this form of protection by the early discovery of fire, one-quarter of a million dollars' worth has been saved through this form of apparatus by the discovery of dangerous heat—heat from which fire would have been generated had not the proper parties been

Digitized by Google

called to the premises and taken the necessary means in reducing the temperature.

This is an important feature of the service, and one which should be realized and appreciated: but, with many, the situation may be likened to the case of the child who obeyed his mother and did not place his hands in the hot coffee pot—the child did uot realize what trouble had been averted by his obedience.

Automatic fire alarm systems prevent fires, and this has been demonstrated repeatedly. It is not an uncommon occurrence for the fire department to be called to a building by this apparatus and to find that probably the occupants had carelessly gone off after coaling up a furnace or stove, leaving all drafts open, with the result that extremely high and dangerous temperature had been generated. Or, possibly, they would discover where a gas jet had been left burning under a vessel for heating glue, or for various other purposes, and this may have heated the woodwork around it to a point of danger. Or, possibly, a stove or furnace funnel, which may have been placed close to the ceiling, or through wooden partitions, may have become dangerously overheated.

These conditions sometimes occur in the daytime, and the occupants know nothing of the danger until the arrival of the firemen.

The public very seldom hears of these important discoveries. Even the official reports may give, as a cause of alarm the alarm, "caused by overheat." They do not add that a fire may have been averted. And many of the newspapers often report the case as "no fire, false alarm."

This also accounts for many false alarms, so called, credited to automatic fire alarm systems.

INTERIOR WIRING.*

BY G. C. ALLINGHAM.

For several years there has been an agitation in favor of concentric wiring with an uninsulated outer conductor, and great efforts have been made to convince central station engineers of the advantages of this system of wiring. But the central station engineers apparently remain unconvinced. It has always appeared to me that the advocates of wiring with uninsulated return look at the question more from the point of view of the wireman (or perhaps I should rather say of the "wiring engineer") than from that of the central station engineer. They hardly seem to realize that the wiring of a building which is supplied from street mains is electrically a part of the distributing network of the central station. If we look at the wiring of a building by itself, and exclude from our consideration anything outside that building, the concentric system of wiring with uninsulated outer undoubtedly has advantages, but, as I shall show presently, these advantages are by no means peculiar to this system. On the other hand, if we regard the distributing system as a whole, by which I mean the whole of the network, from the central station or sub-stations, as the case may be, to the lamps, the use of the uninsulated return conductors is open to many objections.

The very property that is claimed, and justly so, as the great advantage of concentric wiring, namely, that any fault is bound to become a dead short circuit, is a serious disadvantage when we have to deal with a large distributing system, as Mr. Wordingham pointed out in his M.E.A. paper this year. In the case of a three-wire network, with earthed return conductors connected to the middle wire, a single earth on either of the outers will dead short the mains, and interrupt the supply until it can be cut out or burnt out, and it is evident that the danger of interruption of the supply will be much greater in such a case than if the system be entirely insulated from earth, or the middle wire be earthed only at the station, so that it can be temporarily disconnected from earth in case of a fault on one of the outers.

Again, on a large network, different parts even of the middle wire of a three-wire system may be at considerably different potentials, and if uninsulated returns were used, considerable currents might return through the earth and cause electrolytic troubles. Excepting at Guildford, where the system is a very small one, no wiring with uninsulated returns has yet been carried out, except in isolated installations supplied by their own dynamos, or by separate transformers, so that it is impossible to say from actual experience whether the electrolytic trouble is likely to be a serious one or not, but experience with the earth returns of electric tramways shows the kind of things that would be likely to happen. It is true that the drop of voltage on the uninsulated return of a distributing network would probably be less than that on the earthed return of a tramway; but on the other hand, the surface of the uninsulated outer would be very great, and inside a building a comparatively small amount of electrolysis (of a gas-pipe for instance) might do a great deal of damage. Again, there is a danger of the bare outer conductor itself being eaten through, and the breaking of the outer conductor might quite conceivably cause a fire.

At Guildford, although the middle wire of the street mains is bare, it is carefully embedded in bitumen throughout, and in the consumers' premises, which are wired with concentric cable with a bare outer conductor, care has been taken to keep the bare outer out of contact with any gas or water pipes: so that, although a bare outer conductor is used, a sort of attempt is made to insulate it from earth. Is not this a confession of weakness?

The principal advantage usually claimed for concentric wiring is its safety, since the outer exposed conductor is earthed, and it is therefore impossible to get a shock, and any fault must either be a short circuit, or quickly develop into a short circuit, which blows the fuse and cuts off the current until the fault is removed, so that it is impossible for any fault to endure and to cause fire or other damage. What I wish to point out, however, is that exactly the same properties are possessed by any metal-sheathed system of wiring with both conductors insulated, provided that the sheathing is made electrically continuous throughout, and is efficiently earthed, and that one of the wires is earthed at one point either continuously or at frequent intervals.

With such a system of wiring, properly carried out, any fault on either wire is bound to form a connection between it and the metal sheathing, and so earth it, either instantly or very soon, and in any event before any external damage can be done. Now if, for example, the wiring be connected to the neutral and one outer, say the positive, of a, three-wire network, the middle wire of which is earthed at the station, any fault on the positive conductor of the wiring will produce a short circuit, and blow a fuse, and so cut off the faulty conductor until it is repaired. As the negative conductor of the wiring is at or near earth potential, any fault that might occur on it is not likely to be dangerous, but such a fault could not last long if, at intervals, the outers were alternately earthed at the station, the middle wire being, of course, temporarily disconnected from earth meanwhile.

I consider that the greatest possible safety with house wiring would be attained by using double wiring, enclosed throughout in earthed metal sheathing, connected to three-wire mains having a removable earth connection on the middle wire at the station, and by earthing each of the outers (while the middle wire is temporarily disconnected from earth) for a minute or so regularly every day. Any fault in a consumer's installation on either of the outers would instantly cut itself off, and any fault on the neutral would cut itself off next time the outers were earthed at the station, so that the consumer's would be perfectly "self-testing," just as concentric wiring is, and at the same time it would be free from the objections to concentric wiring.

Even where the middle wire is not earthed, almost absolute safety would be attained by earthing each main at the station every day, for a fault on house wiring can hardly do much damage in 24 hours: the damage done by faults is nearly always very gradual, and the catastrophe does not occur until the mischief has been going on for many days or weeks.

It is evident that, to attain safety, the metal sheathing of the wiring must be electrically connected together throughout; in fact, if this is not done, the metal sheathing may constitute a danger rather than a protection, for if a fault occurs on one of the wires, which thus becomes connected to the sheathing, a portion of the latter may become charged above (or below) earth potential, and give people shocks, or, if it touches a gaspipe, it may arc to it, and in time burn a hole in it and ignite the escaping gas.

This is the great defect of the system of wiring in steel conduits with sleeve joints, which has been recently introduced, for the sleeves do not make a good electrical connection between the lengths of tube, and therefore, in my opinion, this system is not to be recommended on the score of safety; the requisite conditions may, however, be fulfilled by the use of iron or steel tubes with screwed couplings, or by lead-covered wires.

My own idea is that lead-covered wires with fibrous insulation are likely to come very much more into use for house work in the near future. They have already almost entirely superseded vulcanized rubber-insulated cables for underground mains, for which purpose they have been found to be cheaper and more durable, and what is true for underground mains is also true for interior wiring. Those who have to do with house-wiring do not generally seem to realize that a lead-coved fiber-insulated cable is much cheaper than an ordinary braided or taped rubber-insulated cable, and that this applies just as much to the smallest sizes of cables as to larger ones, while the lead-covered cable has the further advantage that it can be run without further protection in many places. The price of rubber has been rising steadily for years past, and the rise appears to be likely to continue in the future, so that the saving in cost by using fiber-insulated cables is likely to increase still further. It is now generally recognized that fiber-insulated lead-covered cables are more durable than vulcanized

*From the "Electrical Review," London.

Digitized by Google

rubber-insulated ones for underground work, where the conditions are very much more severe than in housework, so that it is not probable that fiber-insulated cables will be found wanting in durability in interior wiring.

The objection to fiber-insulated cables is that the insulation is hygroscopic, and for this reason the ends of underground cables of this class are enclosed in boxes filled with compound in order to make a water tight seal, and it would be very difficult to effectively seal the ends of all the cables in the wiring of a building in this manner. But my own experience has been that, except in unusually damp buildings, there is no danger of the insulation being damaged by absorption of moisture. I have wired new houses with lead-covered fiber-insulated cables, and left the ends just as they were cut off, without sealing them in any way, to the tender mercies of the plasterers, who have often broken the lead covering of the projecting ends, and yet I have had no single instance of a cable absorbing damp. The only trouble I have had is with surface leakage, which is always greater with metal-sheathed systems of wiring than when no metal sheathing is used, since the sheathing itself forms a good earth close to the bare terminals on the fittings, and shortens the path of the leakage current. This surface leakage sometimes makes it impossible to attain at first in a new house the insulation resistance required by the rules of the supply authorities, but after the house has been occupied for a few weeks, and has become dry, the insulation resistance increases to the normal figure. The surface leakage is no greater with fiber-insulated than with rubber-insulated wires, whether the latter be lead-covered or run in metal tubing, and it is not by any means necessarily an indication of a defect in the wiring; in fact, as I have just pointed out, the systems of wiring which are the safest have the greatest tendency to surface leakage, and the "figure of merit" of an installation is not only not proportional to, but may even be an inverse function of, its insulation resistance. Again, I have found that, with metal-sheathed wiring, the insulation resistance often varies with the weather.

I have usually covered the ends of fiber-insulated house-wires with lappings of insulating strip, such as "Okonite" tape, or with rubber tubing, which I have found quite sufficient protection in ordinary interior wiring. The lead coverings of the wires are easily connected together by copper wires soldered to them with a blowpipe.

Some classes of fiber-insulated cables, particularly paper cables, are impregnated with oil, which gives trouble by becoming fluid in hot weather and running out of the ends of the cables and spoiling the wall-paper. Cables for indoor work should be impregnated with a more solid compound, which will not melt in the hottest summer weather, and there are many fiber-insulated cables made which give no trouble in this respect.

The use of lead-coverd cables gives a very "flexible" system of wiring. In many cases the wires can be run with safety without further protection, and they can be drawn or "fished" under floors, behind partitions and through all kinds of narrow places in a way that would be impossible otherwise; they can be cleared up on the surface, and often most inconspicuously, as they can be run in corners and along edges. Where extra mechanical protection is required, the lead-covered cables may be run in iron or steel tubing, and I have found "Simplex" and similar tubing excellent for this purpose; they can be run on the surface in ordinary wood casing where its appearance is preferred; the lead covering can be additionally protected against corrosion or abrasion where necessary by taping or braiding and compounding; for rough work the cables can be armored with steel wire or strip; and where they are especially exposed to corrosion they can be run in troughing filled with compound. In fact, wiring with fiber-insulated lead-covered cable may be carried out to suit the most varied classes of work, and so as to make a sound job under almost any conceivable conditions, and it therefore seems to me probable that this class of cable will, in the future, become the standard for interior wiring, as it may almost be said to have already become for underground mains.

SPARK-LENGTH AS MODIFIED BY SOLID DIELECTRICS.*

BY W. J. HUMPHREYS.

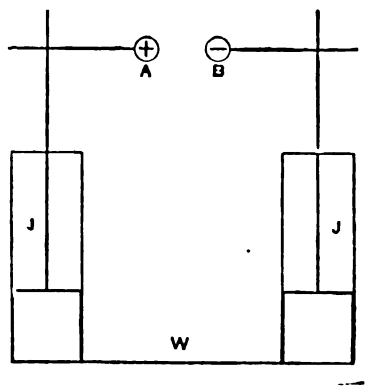
While trying some experiments with an electrical influence machine I noticed that the spark-length was greatly increased by the presence of solid dielectrics, such as glass or ebonite, at certain points near the positive pole. The phenomenon was entirely new to me, and as I was unable to find it described, or even mentioned, in either those books or journals to which one would go for such information, I decided to publish an account of my observations. After my experiments were completed my attention was kindly directed to the fact that Messrs, Queen & Co., of Philadelphia, Pa., furnished an electrical influence machine with radically different poles—one being a metallic sphere while the other is metal plate with an ebonite disk at its center. I have also learned that Prof. Anthony once used a somewhat similar machine that was imported from Berlin about 1870. It seems, therefore, that the action of solid dielectrics on the spark-length has been known for a long while, at least to certain instrument makers, and I venture to publish the following account of my own experiments along this line because I have been unable, after considerable search and numerous inquiries, to find any reference in scientific literature to this interesting phenomenon.

During the course of the experiments several machines were tried and with equal success, but the one commonly used was a two-plate Wimshurst machine, the plates being 20 ins. in diameter of ebonite and furnished with metallic sectors. The accompanying sketch shows an arrangement that gives excellent results, though, as will appear from the experiments, it may be greatly modified and the phenomenon still obtained. J, J are two small Leyden jars, W a wire joining their outer coatings, A and B discharging balls connected one to the positive the other to the negative side of an influence machine or other source of high potential, and also to the inner coating of its respective jar. Let the inner coatings of the jars be oppositely charged, as indicated, and the distance between A and B gradually increased till sparks cease to pass. If now the potential difference be maintained and a glass rod, say, be placed quite near that side of the positive pole that faces the negative, the air will in general break down and allow a full noisy spark to pass. Nothing of the kind happens when the rod is placed next the negative pole, or in fact in any part of the field other than that very near the anode.

* From the "Physical Review."

Various solid dielectrics have been used, all giving the same general result. Among them several kinds of glass, such as lead, soda and different varieties of enamel glass, some in the form of solid rods, others as tubes, even freshly drawn glass fibers of not over three-tenths of a millimeter in diameter, sticks of sulphur, rubber tubes, rods of ebonite, different varieties of wood, and finally, as an extreme case, an ordinary silk thread stretched taut and approximately at right angles to the lines of force. The increase in spark-length was usually very pronounced, often more than doubling the maximum length obtainable under ordinary conditions.

In most of my experiments the machine was kept constantly running at an approximately uniform speed, but this was simply for the purpose of holding the potential difference as nearly constant as possible, and not at all essential to the general phenomenon. The sparks of extra length could easily be obtained after the machine had come to rest, provided they were taken before the potential had fallen too low. The following are among the conditions tested: (1) Polished poles, jars belonging to machine and their outer coatings



connected, inner coatings oppositely charged. Results excellent, best obtained. (2) Polished poles, jars belonging to machine but insulated from each other, inner coatings oppositely charged. Increase in spark-length decided, but volume of spark small. (3) Polished poles of machine oppositely charged, no jars. Increase in spark-length still evident, but volume of spark of course very small. (4) Polished poles, one connected to inner the other to outer coating of a single jar. Results good. (5) Polished poles, one or more jars of large capacity. Results pronounced, but spark-length never so long or so greatly increased as with the jars belonging to the machine. (6) State of atmosphere such as to give only very short sparks. Increase in spark-length decided, but not very great. (7) State of atmosphere such as to give unusually long sparks. Increase in spark length not great, but still evident. (8) Poles separated very widely, beyond the length even of the forced spark. In this case a small spark left the positive pole when the glass or other dielectric rod was brought in proper position and disappeared along numerous little branches. (9) Negative pole polished, positive pole very rough, in fact the broken end of a metal rod. Under ordinary conditions this gave only pinkish brush discharges, except when the poles were very close together, when numerous small, white and somewhat noisy sparks passed. On placing a glass rod next the positive pole, the white and noisy sparks were more than doubled in size and length. Various other

Digitized by Google

more or less important combinations were made, but these are sufficient to indicate the general nature of the phenomenon, the interpretation of which is probably the same, no matter what the conditions under which it is obtained.

Just what the correct or complete interpretation really is, I do not pretend to say, but the increase of the spark-length when the discharge is between two oppositely charged jars, insulated from each other, seems to preclude the assumption that it can be due to oscillations of any kind. Possibly though an explanation is found in the fact that the solid dielectrics used in these experiments have specific inductive capacities greater than that of air, and consequently produced corresponding local concentrations of the lines of force, which concentration extended to a greater or less extent to the surface of the electrode when the dielectric was in its immediate neighborhood. It may be that the increase in the spark-length was due to this local increase of the electromotive intensity, but in framing an hypothesis to explain it the fact that this increase must be next the anode has to be kept in mind. For the sake of binding these and other experiments, more or less closely together, I suggest the following hypothesis: The dielectric between two poles is most sensitive to electrical disturbances at points next the anode. The following are some of the facts that seem to support this idea. (*a*) The spark-length is increased by the presence of a glass rod say next the anode, but not affected when the rod is in any other part of the field. (*b*) The greater the increase of the spark-length the nearer the glass rod must be brought to the positive pole. (*c*) The greatest increase of spark-length is obtained with a glass rod of certain size, other things being equal. That is, the rod must not be either too large or too small for best results. (*d*) When glass fibers are used they must be brought very near the pole, usually nearly or quite in contact with it. (*e*) The same phenomenon follows when insulated conductors are used instead of glass or other dielectric. With the view of testing this idea I tried, among other things, the effects of dielectrics of widely different inductive capacities, but otherwise approximately equal. The substances used were: (*a*) A small thin-walled test-tube, empty. (*b*) Similar tube part filled with water. (*c*) Similar tube part filled with metal. The results were not conclusive, the increase in the spark-length remaining nearly the same, with, if anything, the advantage in favor of the tube part filled with water, but this was not sufficiently pronounced to warrant deductions. Again the fact that insulated metal rods act no better than glass rods does not seem to be fully in accordance with the above assumption. These, however, are the only experimental objections I am aware of, and it may be that they are by no means fatal. In further support of this hypothesis we have the increase of spark-length caused by a small spark drawn from the negative pole of two oppositely-charged Leyden jars when their outer coatings are connected, and also Faraday's experiments on spark-lengths between spherical electrodes of different sizes. In speaking of these experiments of Faraday, J. J. Thomson says: "We may express this result by saying that when the electric field is not uniform the gas does not break down so easily when the greatest electromotive intensity is at the cathode as it does when it is at the anode." It will be noticed that the hypothesis used to explain these experiments is only an adaptation of this sentence of Thomson's. Whatever the real action of solid dielectrics in increasing spark-length may be, it is a phenomenon of the anode, and to that extent indicates a greater sensitiveness of the air about this pole to electrical disturbances. It would be interesting, but probably of little use at present to speculate on the cause of this localized sensitiveness in the dielectric. Possibly it was due to the formation of Grothus' chains and the clustering of different types of ions about the two poles.

WHAT MARCONI HAS ACCOMPLISHED.

As the subject of wireless telegraphy has not yet apparently lost interest for the general reader, says Prof. J. A. Fleming in the London "Times," I venture to ask a little space to make known for the first time some recent achievements by Mr. Marconi which have astonished those who have been allowed to examine them. Every one is aware that in his system of electric wave telegraphy an important feature is the employment of an elevated conductor, which generally takes the form of a wire suspended from a mast. When Mr. Marconi attracted attention by his feat of establishing communication across the Channel without wires, critics raised a not altogether valid argument against its commercial utility, that a wave or signal sent out from one transmitter would affect equally all received within its sphere of influence, and hence the privacy of the communication would be destroyed. No one felt the force of this objection more strongly than the distinguished inventor himself, whose original work has caused so many others to attempt to follow in his steps. For the last two years he has not ceased to grapple with the problem of isolating the lines of communication, and success has now rewarded his skill and industry. Technical details must be left to be described by him later on, but meanwhile I may say that he has modified his receiving and transmitting appliances so that they will only respond to each other when properly tuned to sympathy. I am well aware that other inventors have claimed to be able to do the same thing, but I do not fear refutation in saying that no one has given practical proof of possessing a solution of this problem which for a moment can compare with that Mr. Marconi is now in a position to furnish.

These experiments have been conducted between two stations 30 miles apart, one near Poole in Dorset and the other near St. Catherine's in the Isle of Wight. At the present moment there are established at these places Mr. Marconi's latest appliances, so adjusted that each receiver at one station responds only to its corresponding transmitter at the other. During a three days' visit to Poole, Mr. Marconi invited me to apply any test I pleased to satisfy myself of the complete independence of the circuits, and the following are two out of many such tests: Two operators at St. Catherine's were instructed to send simultaneously two different wireless messages to Poole, and without delay or mistake the two were correctly recorded and printed down at the same time in Morse signals on the tapes of the two corresponding receivers at Poole.

In this first demonstration each receiver was connected to its own independent aerial wire hung from the same mast. But greater wonders followed. Mr. Marconi placed the receivers at Poole one on the top of the other, and connected them both to one and the same wire, about 40 feet in length, attached to a mast. I then asked to have two messages sent at the same moment by the operators at St. Catherine's, one in English and the other in French. Without failure each receiver at Poole rolled out its paper tape, the message in English perfect on one and that in French on the other. When it is realized that these visible dots and dashes are the results of trains of intermingled electric waves rushing with the speed of light across the intervening 30 miles, caught on one and the same short aerial wire, and disentangled and sorted out automatically by the two machines into intelligible messages in different languages, the wonder of it all cannot but strike the mind.

Your space is too valuable to be encroached upon by further details, or else I might mention some marvelous results, exhibited by Mr. Marconi during the same demonstrations, of messages received from a transmitter 30 miles away and recorded by an instrument in a closed room merely by the aid of a zinc cylinder, 4 ft. high, placed on a chair. More surprising is it to learn that, whilst these experiments have been proceeding between Poole and St. Catherine's others have been taking place for the Admiralty between Portsmouth, and Portland, these lines of communication intersecting each other; yet so perfect is the independence that nothing done on one circuit now affects the other, unless desired. A corollary of these latest improvements is that the necessity for very high masts is abolished. Mr. Marconi now has established perfect independent wireless telegraphic communication between Poole and St. Catherine's, a distance of 30 miles, by means of a pair of metal cylinders elevated 25 ft. or 30 ft. above the ground at each place.

I need not enlarge on the possibilities thus opened out for naval and military purposes. The importance of this practical solution of the problem of independent electric wave telegraphy, in which each wireless circuit is as private as one with a wire, is obvious without comment. My desire is solely to mention the above facts for the benefit of general readers, whose minds will thus perhaps be eased of any doubts lest this brilliant application of electrical discoveries should, like some others, fall short in satisfying the requirements of practical use and be relegated to the region of imperfect inventions or unfulfilled hopes.

MARKET VALUE OF A SUCCESSFUL PATENT.*

What is the market value of a successful patent? The question is a wide one; and one, moreover, upon which much ink and thought might be expended without (in all likelihood) arriving at any really satisfactory answer. The purpose, or purposes, of the patent, the area over which it is intended to be spread, its actual value for practical purposes, etc., are prominent "points" which would all require to be considered by anyone who might choose to handle this thorny theme. When he did consider the subject in all its phases he would doubtless experience great difficulty in any straightforward attempt he might make to appraise its value from a purely commercial standpoint. There is, as we all know, no set "rule" to go by in dealing with a matter of this kind, but while that is so, there can be no doubt of this, viz., that some of our present-

* From the "Engineer and Iron Trades Advertiser," Glasgow.

Digitized by Google

day patentees have succeeded in realizing large sums (in a few instances small fortunes) from their respective inventions.

It would not be easy to mention the exact or even the approximate sums earned by the world's leading inventors during the present generation, but we are pretty safe in placing Edison in the front rank, closely followed, we might say, by Maxim, then by Kelvin, and thereafter by perhaps half a dozen others. Amongst the others hinted at might be placed Marconi, the young Italian genius, whose marvelous system of wireless telegraphy has set the mechanical world on tiptoe. Marconi, besides demonstrating the practical utility of his novel discovery—or invention—for manifold purposes, has contrived to have same placed in remunerative quarters. Thus, he is reported to have disposed of his "patent rights" in America for one million dollars and a large royalty. And now we hear that the royalty to be paid him by the British Government for his apparatus on warships is £100 per annum for each ship, and that twenty-five sets have been ordered.

Truly, the calling of the modern inventor has become a singularly lucrative one; we are, of course, speaking, of the successful inventor of the hour. We know quite well that the unsuccessful inventor (who, numerically speaking, far outweighs the former named), could tell an altogether different tale. Their "tale" has been told in hundreds of cases, as every student of biography knows the "little story" has, in not a few instances, been a sad one; one calculated to touch the sympathetic heart, and to cause the reflective reader to wonder why men of superior native ability (as inventors invariably are) should so long court a forlorn hope, for that is what a big proportion of such have done. Not only so, but these persons are often so completely taken up with their peculiar task, that is, with the perfecting of their respective device, that they not infrequently neglect the ordinary duties of life. Their daily work is performed with a grudge, and sometimes entirely neglected, while their family affairs are ignored.

A careful study of his—the unsuccessful inventor's life-story, however, brings with it its moral, a moral which all aspiring young inventive geniuses would do well to take seriously to heart. The moral is, first perform thy daily toil, next tackle thy pet hobby; for, the working out of any new idea, either in mechanics, art, or science, (or in literature for that matter), ought always to be done during one's leisure hours, thus making the self-appointed task, which may after all yield naught substantial—a hobby, rather than allowing the prosecution of same, as many have done to their sorrow and loss, to absorb the whole of one's waking hours. We are, we need scarcely state, speaking just now to those who require to earn their daily bread by the sweat of their brow. It is different with those inventors who have a private competence to "lean" upon the while. But these, we fear, be few in number.

Exports of Electrical Material from New York.

The following are the exports of electrical material and machinery, from the port of New York, for the week ended October 10:

Amsterdam, 1 box, $13; Antwerp, 19 cases, $3,003; Australia, 21 packages, $1,010; 6 boxes motors, $4,080; Brazil, 2 cases, $84; 23 packages, $2,500; Bordeaux, 5 cases, $491; Bremen, 4 cases, $357; British East Indies, 18 packages, $2,315; British West Indies, 13 cases, $269; British Possessions in Africa, 2 cases, $108; British Guiana, 41 packages, $1,417; other British Possessions, 77 packages, $2,650; Bristol, 74 cases, $4,700; 22 reels electric cable, $5,767; Brussels, 1 case, $28; 3 packages trolley wagons, $250; Budapest, 8 packages, $440; Central America, 55 packages, $2,494; Chili, 4 cases, $117; Cuba, 55 packages, $1,529; Dublin, 3 reels electric cable, $2,011; Dunkirk, 44 cases, $790; Florence, 3 cases, $194; Flushing, 3 boxes, $135; Glasgow, 15 packages, $15,336; 4 reels electric cable, $16,835; 7 cases $228; Hamburg, 74 packages, $10,759; Havre, 3 cases, $144; 125; packages, $2,456; 6 cases automobiles, $2,814; Leith, 6 cases, $120; Liverpool 35 packages, $6,010; 24 cases, $1,199, London, 284 packages, $41,608; 6 cases motors, $475; 93 trolley poles, $1,768; Manchester, 23 packages, $4,060; 20 packages automobile parts, $1,000; Marseilles, 27 cases, $1,853; Mexico, 33 packages $1,742; Middlesborough, 1 crate, $20; Newcastle, 12 cases motors, $1,866; Newfoundland, 1 package, $20; New Zealand, 4 packages motors, $250; Nova Scotia, 3 packages, $23; Peru, 15 cases, $464; Preston, 3 packages, $54; Riga, 7 cases, $1,155; Santo Domingo, 18 packages, $462; Southampton, 2 cases, $38; St. Petersburg, 6 cases, $369; U; S. Colombia, 3 cases, $44; Venezuela, 44 packages, $631.

PERSONAL MENTION.

Mr. Fred Leonard Bloss, who was recognized as one of the leading electricians of the West, recently died at his father's home in Kansas City, Mo.

Mr. H. R. Bostwick, the San Franciscan who recently completed an electric railway at Seoul for the Emperor of Corea, returned a short time ago to San Francisco.

Mr. W. H. Conrad, formerly with the Philadelphia & West Chester Traction Company, was recently appointed superintendent of the electrical department of the Newton Electric Street Railway Company.

Mr. William H. Wilson, superintendent of the Camden, Gloucester & Woodbury trolley road, which is now operated by the South Jersey Electric, Heat, Power & Traction Company, has been transferred to the superintendency of the electric light works in Gloucester, N. J., which is also under the control of the above corporation.

Mr. Lewis A. Goudy of Portland, Me., has been elected president of the New England Automatic Telephone Company, of which he was already general manager.

Mr. Charles H. Duell, the Commissioner of Patents, will soon resign to engage in law practice in Syracuse, N. Y.

Mr. George Treadway Thompson, president of the Denver (Col.) Gas & Electric Cmopany, died recently, aged 31 years.

COMING ELECTRICAL EVENTS.

American Street Railway Association—Will meet in Kansas City, Mo., Oct. 16-19, 1900.

Roentgen Society of the United States—Will meet in New York City Dec. 13-14, 1900.

INCORPORATIONS.

The Bishop Electric Company, New York City. Capital stock, $50,000.

The Dayton & Mayesville Electric Railway Company, Morrow, O. Capital stock, $10,000.

The Hamilton Electric Supply & Construction Company, Limited, Hamilton, Ont. Capital stock, $40,000.

The Auto Electric Shunt Company, West New Brighton N.Y. Capital stock, $5,000. Directors: E. R. Cliff and A. B. Proal, Jr., West New Brighton; F. W. Wise, Port Richmond.

The Modern Engineering Company, Wellsville, O.—to do a general mechanical and electrical engineering business. Capital stock, $150,000. Incorporators: C. R. Dallas, H. L. Ken, G. B. Thurber, C. E. Reed, all of Pittsburg, Pa., and T. Charlton of Chicago, Ill.

The Montgomery Power Company, Amsterdam, N. Y.—to furnish electricity for producing, light, heat and power and for lighting the streets of Amsterdam, Johnstown, Gloversville and other places. Capital stock, $100,000. Directors: William K. Archbold, Paul T. Brady, Robert E. Drake, Syracuse; W. Barlow Dunlap, William B. Charles, Robert R. Reed, Amsterdam, and Jacob Snell, Fonda.

The Broadalbin Electric Company, Broadalbin, N. Y.—to furnish light, heat and power for the village of Broadalbin Capital stock, $25,000. Directors: Henry B. Dakman, E. H. Tucker and T. Arthur Farley, Brooklyn; L. U. Shafter, Rockville Center, and Charles F. Lehman, Smithtown, L. I.

ELECTRICAL PATENT RECORD.

[This department is edited by OSCAR A. MICHEL, Solicitor and Attorney for AMERICAN AND FOREIGN PATENTS, at 302 and 304 Broadway (Room 1204), New York City, also at 639 F street, N. W., Washington, D. C., who has been identified with this work before the U. S. Patent Office for more than fifteen years. Any inquiries upon the above subject as well as printed publications containing all information regarding the cost of United States and Foreign Patents, Trade Marks, Designs, etc., will be given free upon application by addressing OSCAR A. MICHEL, Nos. 302-304 Broadway, New York City, N. Y., or 639 F street, N.W., Washington, D. C. Copies of any patent published can be furnished upon payment of ten cents. When ordering give name, date and title of invention wanted.]

LETTERS PATENT ISSUED OCTOBER 9, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

659,335. Base for Trolley-Poles. Andrew C. Wolfe, Freeport, Pa., assignor of one-third to Joseph F. Hewitt, Allegheny, Pa. Filed Dec. 26, 1899.

659,355. Trolley Finder and Guard. Harry C. Williams, Pasadena, Cal. Filed April 26, 1900.

659,550. Electric Railway. James D. Robertson, La Salle. Ill. Filed Jan. 31, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

659,268. Glower Heating Apparatus for Electric Lamps. John Van Vleck and William N. Stevens, New York City. Filed April 27, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

659,244. Circuit-Controller. Adam Lungen, New York City. Filed Feb. 23, 1900.

659,357. Apparatus for Locating Faults in Electric Circuits. William E. Athearn, New York City. Filed Jan. 23, 1899.

659,389. Electric Meter. Thomas A. Edison, Llewellyn Park, N. J. Filed Sept. 24, 1898.

659,417. Self-Adjusting Circuit-Breaker for Electrical Welding Machines. John C. Perry, Clinton, Mass. Filed March 26, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

659,269. Annunicator for Telephone-Exchanges. Benjamin Waller, Detroit, Mich. Filed Dec. 20, 1897.

659,588. Telephone-Switchboard Annunciator and Jack. Charles T. Mason, Sumter, S. C. Filed Nov. 28, 1899.

MISCELLANEOUS.

659,409. Electric Bipolar Dilator. Charles L. Mosher, Chatham, N. Y. Filed Aug. 25, 1900.

659,443. Commutator and Method of Making Same. Edwin R. Gill, New York City, assignor to the Invention Developing Company, of New Jersey. Filed March 1, 1900.

659,467. Electrical Illuminated Button. Walter A. Church Pittsburg, Pa. Filed Dec. 9, 1899.

659,479. Electric Program-Clock. Harry F. Jordan, Chicago, Ill., assignor of one half to Albert L. Bently, same place. Filed Dec. 15, 1899.

659,493. Safety Device for Elevators. George E. Shepler, Pittsburg, Pa. Filed June 3, 1899.

659,499. Signal System. Isaac W. Ullman, New York City. Filed Nov. 17, 1899.

659,506. Magnetic Regulator for Galvanometers. James J. Bradley, Newark, and Louis M. Pignolet, Orange, N. J.; said Bradley assignor to said Pignolet. Filed April 13, 1899.

659,533. Electrically Controlled Coin Feeding Appliance for Vending-Machines. Richard Kann, Jena, Germany. Filed March 8, 1900.

659,539. Supporting Device for Electric Motors. Charles A. Lindstrom, Chicago, Ill., assignor, by direct and mesne assignments, to the Hewitt Lindstrom Motor Company, same place. Filed Oct. 16, 1899.

659,544. Telegraph System. Frank D. Pearne, Davenport, Iowa. Filed April 16, 1900.

659,559. Lightning-Arrester. Charles M. Taylor, Georgetown, Ky. Filed June 12, 1900.

659,605. Electric Thermostat. Leonard H. Des Isles, Cambridge, Mass. Filed Jan. 10, 1900.

659,631. Device for Removing and Replacing Incandescent Lamps. Roch Croteau and Richard J. Messier, Denver, Col. Filed June 11, 1900.

Digitized by Google

THE TELEPHONE WORLD.

Telephone Improvements.

W. H. Baker, the general manager of the Diamond State Telephone Company, has lately been in Easton, Md., where the company has a force of fifty men at work rebuilding the telephone exchange and equipping it for 200 telephones and substituting a modern and best-approved apparatus for that hitherto used. Copper wire is substituted for iron wire on the main routes. Easton will have direct connection without break by copper wire with Denton, Centreville and Chestertown. A copper wire will run direct from Easton to Georgetown, Del., connecting with copper wire circuits through Delaware to Wilmington and Philadelphia. Another circuit goes direct from Easton to Cambridge, Md., where the exchange and service are being rebuilt as in Easton. In making the improvements and betterments the company will spend from $15,000 to $20,000.

The cable across the bay will run from a point on the Chester River side of Kent Island, above Love Point, to Sandy Point, on the western shore.

Asked how the cable could be protected from being broken by oyster dredging, Mr. Baker said that the bottom selected for the cable is a strip where there are no oysters for three-quarters of a mile on each side of the cable's path and where, in the shallow water, there are rocks the dredgers avoid. The Secretary of War has given permission to the telephone company to buoy the cable's site. A direct telephone service from Washington to the Delaware breakwater is appreciated by the War Department. As to oyster dredgers, one thing they always avoid is getting their machines fouled by any stationary submarine object. They will evade raking their dredges across a cable if they know where it is.

One object of the telephone company in the work it is doing now is to connect together every town, village, and hamlet on the Peninsula. Another is to get as good long-distance telephone service for the Peninsula as any section of the United States has.

The board of fire commissioners of San Francisco, Cal., has hit upon a novel plan whereby a considerable sum of the appropriation allowed it for the maintenance of the fire department for the fiscal year 1900-1901 may be saved. The board of supervisors recently decided that the telephones in use in the several departments must either be paid for out of the regular appropriation or removed, and the fire department came under this order. The battalion chiefs had 'phones in their residences, and the board recognizes the need of the same, but could not see its way clear to pay for them. It is now proposed to let the telephone company take the telephones out and have a "local" system introduced by the department of electricity. Those in authority say there is no apparent need why an engine house should be connected with the entire city at great cost to the municipality. The plan has not been fully decided upon as yet, but is very favorably considered.

Work on the new line of the Home Telephone Company in North Tonawanda, N. Y., is progressing rapidly, and President A. R. Smith recently said that the system will be in full operation with at least 300 subscribers by December 1. With the exception of putting in the instruments, all of the work in the village of Tonawanda is now finished. No telephones will be installed in Tonawanda until the line is ready for operation in North Tonawanda, and then all of the instruments will be put in at once. The equipments for the exchange have arrived and are being put into the central office. Work has been started on a toll line between North Tonawanda and Niagara Falls, the line being begun at both ends. President Smith also says that the Lockport Home Telephone Company expects to finish the line in that city by February 1, and then a toll line between Lockport and North Tonawanda, and between Lockport and Niagara Falls will be built.

W. H. Blake and others, who conduct an independent telephone exchange at Cheboygan, Mich., have appealed to the common council at Sault Ste Marie in the same State for a franchise to operate a telephone exchange in that city. There have been many complaints against the service rendered since the consolidation of the two companies which formerly existed there, and this new movement is the outcome.

Several stockholders of the Mutual Telephone Company of Des Moines, Ia., have subscribed to the preferred stock as planned at the last meeting of the directors. No systematic canvass has been made to secure signatures, but it is thought men will be obtained for this work and then the preferred stock will be found of ready disposal.

The Michigan Telephone Company has reduced the rate for talks between Detroit and Pontiac to ten cents for a five minute use of the wire.

The New England Telephone Company will place its wires underground on the main streets of Laconia, N. H.

'Phone Service for Mines.

It is learned that the newly incorporated Mountain Telegraph Company is a project controlled by the officials of the Colorado Fuel & Iron Company. It is capitalized at $1,000,000, and it is the intention of the company to construct a telegraph and telephone service of its own.

The lines will connect all the works of the company located in Colorado, New Mexico and Wyoming. In this way the mines as well as the plants will be brought into close connection with the central management.

For several months P. L. Spooner, of Madison, Wis., has been at work perfecting a township telephone company, with a field of operations intended to cover the State of Wisconsin. He now announces the organization of the Farmers' Telephone Construction Company, with a capital of $500,000. The novel plan of giving every farmer a perfect telephone service at low rates has been the subject of careful study on the part of the organizers for the past three years. They have at last hit upon a practicable plan that will give every country-dweller the benefits of complete telephone service at small cost. The company will begin operations at once, and expects to put in a number of township systems in Southern Wisconsin within the next few months. Later it will extend its operations to other States.

Twenty-six poles set by the Independent United States Long Distance Telephone Company of Newark, O., and three belonging to the Granville local exchange were cut down a short time ago, and wires were cut as a climax to the bitterest warfare ever waged against an Ohio corporation. The people declared that poles were set too short and protested in vain against the destruction of shade trees by the trimmers. Trouble in erecting the poles recently was prevented, but when trimming began and people saw their handsomest trees doomed they rose up as one man. Mayor Lewis headed them and swore in many deputy marshals, and ten telephone men were arrested.

The Cumberland Telephone Company of Shelbyville, Tenn., having advanced rates to $2 50 per month, the business men of that town have ordered their 'phones taken out, and this has been done. Lately an independent telephone company was formed there, and it is said will soon be ready for business at much lower rates than those demanded by the Cumberland Company. This independent company has ample capital, it is claimed, and has already secured the rights of way along the streets.

The Belmont Telephone Company seems to be successful in the way of securing franchises in Belmont County, O., as it has not yet been refused in any part of the county, although the Bell Company has been fighting it. It is said the latter company was recently turned down at St. Clairsville and also at Flushing, O., which has a local company of its own which will probably be connected with the Belmont Company. It will give the Flushing Company connection with the whole county and Wheeling, W. Va., which will be a great convenience. The new company has received much encouragement in Wheeling, almost all business houses having signed a contract.

The Union Traction Company of Marion, Ind., is preparing to run its cars by a train dispatcher, who will use the telephone. A telephone will be located at each of the sub-electric plants, and the cars will be followed in their movements as are those of a steam railroad. The company has found that the signal system it is using is not productive of good speed. The construction of the telephone lines will begin shortly.

The Exchange Telephone Company which is building a line to connect the independent line in Moundsville, W. Va., with its system in the lower end of Marshall County, has the work about completed.

The Hudson River Telephone Company is about to make many improvements in its plant at Hoosick Falls, N. Y. It will rebuild the exchange and make an entire metallic circuit, and a new modern switchboard will be placed in its office.

Trinity, Tex., will soon be equipped with one of the best telephone systems in the State. The Southern Telephone Company is putting the system in. It has arranged with the Southwestern for long-distance connections.

Auburn, Me., has had a number of new telephones put in recently.

A telephone system is being put in throughout the City of Edgar, Neb. The company consists of Edgar business men and the system is the Central Telephone System of St. Louis.

The Georgia Telephone and Telegraph Company of Savannah has just issued a new list of subscribers which shows that the number has increased 115 per cent since the first book was issued last May. It is a record of which the company is justly proud. Since the company commenced business it has been forced to make one addition to its switchboard, and the outlook is that another and even larger addition will have to be made within the near future. Despite the number of 'phones that have already been put in the company has still contracts for 150 or more instruments and the orders that come in daily keep the list up to this mark, though between eight and ten 'phones are put in each day. Some of the underground cables have already been completely used up and others will have to be provided to accommodate the new 'phones. This additional cable has been ordered and will be drawn in as soon as it arrives. The company is also building a line between Savannah and Meldrim in order to get a direct connection with Statesboro and other towns along the Savannah and Statesboro road. This connection is now being made via the line of the Seaboard Air Line, but has grown too large to be handled in connection with the other business of that line, hence the new connection.

The Chester County Telephone Company's line, between West Chester and Kennett Square, Pa., was opened for business a short time ago and the service afforded is of the best. Work is being pushed on the extension of the line to Oxford and other places. At the present time 18 'phones are working in Kennett Square and a number of others will soon be placed in service. There will be a large number in Oxford, West Grove and Avondale when the line is open for service.

Under the management of Superintendent Frank J. Kelley the Albemarle Telephone Company lately opened its long-distance line to Richmond, Va., and now Charlottesville and the capital city are on speaking terms. The Albemarle Company has also opened connection with the Louisa Telephone Company, and the people now talk with Gordonsville, Somerset and many points in Fluvanna County. The above connections will give the Albemarle Telephone Company upwards of 2,000 additional connections.

There is evidence to show that the Massachusetts Telephone Company, which started in to do business a year or so ago, and which then apparently retired from the field, has taken on a new lease of life, since it has been heard from again in Brockton, Mass.

The Susquehanna Telephone and Telegraph Company held a meeting last week and appointed a committee to purchase of N. S. Williams the telephone line from Windsor and vicinity to Susquehanna, Pa.

T. D. Crow, a stockholder and general manager of the Butler Telephone Company at Mountain City, Tenn., has sold his interest to A. H. McQueen.

The Michigan Telephone Company has let contracts for the erection of two brick exchange houses at Grand Rapids to cost $13,000.

The Erie Telephone system made a net gain of 3,022 subscribers in September. The total number connected September 30 was 134,570. The number waiting connection, 3,672.

The People's Telephone Company, of Chatfield, Minn., lately amended its articles increasing the capital stock from $50,000 to $75,000.

J. T. White, of Louisiana, is preparing to construct a telephone line to Murfreesboro in Pike County, Ark., and all intermediate points.

The Flushing, O., Telephone Company, has increased its capital stock from $3,000 to $10,000.

TELEPHONE INCORPORATIONS.

The Carnot Telephone Company, Carnot, Pa. Capital stock, $1,000.

The Oil Belt Telephone Company, Fostoria, O. Capital stock, $10,000.

The Starline Telephone Company, Russelville, Ind. Capital stock, $192. Directors: C. H. Ramsey, Leonard Wilson, W. C. Boyd, J. W. Whitled and C. F. Fordice.

The Delmar & Hoytville Telephone Company, Harrisburg, Pa.—to maintain telephone lines in Lycoming, Tioga and Potter Counties. Capital stock, $2,000,

The Greenfield Telephone Company, Greenfield, N. Y. Capital stock, $1,000. Directors: C. E. Latham and Henry Menshausen, Porter's Corners, and J. S. Robinson, Greenfield Centre.

GENERAL NEWS.

What is Going On in the Electrical World.

LIGHTING.

Barberton, O.—The question of Barberton owning its own electric light plant will be submitted to a vote of the people at the November election.

Benson Mines, N. Y.—Albert E. Clark will equip Post & Henderson's mills at this place with an electric lighting system.

Beresford, S. D.—John Croskey has decided to put in an electric light system and expects to have it in operation by December 1.

Big Rapids, Mich.—This city is about to advertise for bids for lighting the city.

Blaine, Wash.—This place will soon have an electric light plant. L. W. Davis is interested.

Boonsboro, Md.—The burgess and commissioners recently entered into a contract with L. A. Funk to light the town by electricity for five years for $310 a year.

Cienfuegos, Cuba.—Bids are asked until October 26 by the municipal council for electric lighting.

Clayton, Ala.—This city is considering the question of erecting an electric light plant.

Columbia, La.—The people of this town are considering the question of putting in an electric light plant..

Cumberland, Md.—The Edison Electric Illuminating Company of this city has voted to issue $35,000 of bonds to build the steam pipe system now being laid in the streets and to make improvements to the electric light plant.

Detroit, Mich.—The public lighting commission is preparing to install a new triple expansion engine to increase the capacity of the plant.

Franklin, Ind.—The Franklin Water, Light & Power Company will soon let contracts for an electric light plant to cost $30,000.

Greenville, N. C.—The citizens of this place are agitating the question of erecting an electric lighting system.

Highland, Ill.—At the city council meeting held here recently it was decided to erect an electric light plant.

Ironwood, Mich.—The machine shops and electric light plant of the Oliver Mining Company of this city, recently burned. Loss $25,000, covered by insurance.

Ithaca, N. Y.—The citizens are agitating the question of erecting a second electric light plant and the establishment of a heating and power supply plant in this city.

Kutztown, Pa.—The Keystone Electric Light & Power Company has been organized here with D. P. Grim president.

Luzerne, Pa.—The West Side Electric Company is changing the old Heissler system of lighting for a system called the Stunter alternating system. The lights are better in every way.

Matanzas, Cuba.—The city council is now advertising for a proposition for an electric lighting and electric railway franchise.

New Haven, Conn.—The Consolidated road will soon establish an electric light station in this city, from which will be furnished all the power to be used for illuminating its own property.

New Iberia, La.—This city has voted to build an electric light plant.

Oelwein, Ia.—The Oelwein Light, Heat & Power Company has purchased the plant of the Oelwein Electric Light & Power Company. The new company intends to greatly improve the plant in the way of adding to the machinery and equipment.

Pembroke, Ky.—W. S. Bumbus will erect an electric light plant here.

Philadelphia. Pa.—The Ambler Electric Light Company has increased its rates because the borough has levied a tax of $1 on each pole in the borough.

Pittsfield, Mass.—The Eureka Electric Company will wire St. Charles' Church for electric lights.

Port Washington, N. Y.—Robert La Porte an electrician of Tremont, N. Y., was here a short time ago and said if he can secure the franchise from the old company he will build a plant and not only light this village, but he will extend the line to Manhasset and Sands Point.

Renton, Wash.—This place, Auburn and Issaquah are soon to be lighted from the Snoqualmie plant, the main transmission line, which passes through the towns in question, being tapped for the purpose.

San Diego, Cal.—A duplicate lighting plant is being installed by the San Diego Gas & Electric Light Company, involving an expenditure of $25,000.

Steamboat Springs, Col.—This newly incorporated town has granted to G. H. Smedley a twenty-year electric light franchise. Work on the construction of the plant will be commenced at once.

Westville, N. J.—Another movement has been started here to get electric lights.

STREET RAILWAYS.

Akron, O.—Capitalists of this city and Cleveland have combined their means in the formation of a company for the purpose of building an electric railway from Lima south to Wapakoneta, a distance of 29 miles, and the company will soon be incorporated under the name of the Western Ohio Electric Railway Company. W. Christy of this city is one of the projectors. The concern will be capitalized at $500,000.

Albany, N. Y.—The Albany County Railroad Company, a street surface railroad to be operated by electricity, with a capital stock of $20,000, was incorporated on October 10, with the Secretary of State. The length will be about three-quarters of a mile.

Asheville, N. C.—A trolley line from this place to Sulphur Springs is to be built by R. P. Hayes and others.

Bel Air, Md.—At a recent meeting of the town council the Bel Air & Havre de Grace Electric Railway Company was granted the franchise of running cars through the streets of this place.

Boston, Mass.—The syndicate headed by J. F. Shaw & Co. of this city has secured the right of way from Trenton to Philadelphia for its new trolley system.

Brookfield, Mo.—The proposition of building an electric road between this town and Keytesville is being revived by the local commercial club and the citizens of Keytesville. O. B. Anderson, of Keytesville, is the chief promoter.

Chillicothe, O.—An electric road is to be built from this city to Hillsboro via Bainbridge. Eastern men are to furnish the money, and the Chillicothe Company builds the road. Work will begin January 1.

Colt's Neck, N. J.—John F. Beckman owns two farms between here and Scobeyville. He says that if the proposed trolley line from Freehold to the shore comes through this place and Scobeyville he will give a right of way through his lands and also contribute cash toward the enterprise.

Concord, N. H.—At the annual meeting last week of the stockholders of the Concord & Montreal Railroad it was unanimously voted to authorize the building of a branch from this city to Hudson, to be operated by electricity, and to issue bonds for the construction thereof to an amount not to exceed $1,000,000.

East Glastonbury, Conn.—The officials of the Hartford Street Railway Company visited this place a short time ago to consider the feasibility of extending the trolley line from Glastonbury to this village.

Holly, Mich.—The council and town board lately granted an electric road franchise to the Egyptian Portland Cement Company to connect its two factories to be built a mile east of this place and two miles west of Fenton. The road will be nine miles long.

Indianapolis, Ind.—The Street Car Company of this city will expend $500,000 in revolutionizing its power and feed system. By establishing a storage battery enough electricity can be stored to furnish power for the whole system for some hours should the machinery at the power house become impaired.

Larchmont, N. Y.—The work of changing the horse railroad to an electric line is in progress in the Manor part of this place.

Plainfield, N. J.—The Riker-Hine syndicate has combined all its trolley interests in the vicinity of this city under the corporate title of the Elizabeth, Plainfield & Central Jersey Railroad.

Redkey, Ind.—The city council granted F. G. Brownell a franchise to run his new interurban electric line through the streets. Work will soon begin on its construction.

Sharon, Pa.—Townsend, Reed & Co., of Chicago, which has absorbed the Valley street railway franchises of the Sharon & Wheatland Electric Line and rights in the Youngstown-Sharon proposed electric road, expects to expend $450,000 for construction of a new interurban system between here, Sharpsville, Wheatland and Youngstown.

Way Cross, Ga.—At a special election held a short time ago in this city a 50 year franchise was granted to the Way Cross & Suburban Railway Company for constructing and operating an electric street railway.

Wilmington, Del.—W. H. Quigg, of Philadelphia, Pa., was awarded the contract to build a new trolley line in this city.

MANUFACTURING.

Decatur, Ill.—The plant of the Feries Manufacturing Company, makers of electric lamp holders, was recently destroyed by fire. Loss $40,000, partly covered by insurance. The plant will be rebuilt at once.

Far Rockaway, N. Y.—A new factory has been erected by the Rockaway Motor Company, a concern formed for the purpose of building electric motors and launches. The company has an order for twenty electric launches, which are to be delivered to a Connecticut firm before spring.

Knoxville, Tenn.—Rodgers & Co., manufacturers of specialties, lately installed an electric plating plant, which can be used to plate all kinds of metals.

Warren, O.—The Economy Electric Company of this city was lately organized by P. L. Webb, George H. Jones, George B. Sawyer, J. W. Powers and H. W. Smith, Jr. It will make dynamos, insulators, motors and electric supplies of all kinds on a capital stock of $50,000.

COMPANY MATTERS.

Milwaukee, Wis.—The Milwaukee Electric Railway & Light Company announces that contracts for the erection of a new $800,000 four-story central car barn and general office building will be let within a short time.

New Haven, Conn.—The Dennison Electrical Company of this city has filed a petition in bankruptcy in the United States Court. The liabilities are given as $24,618.66, and the assets $2,961.13.

New York City.—At a meeting of the board of directors of the Sprague Electric Company, held recently, the following officers were elected for the ensuing year: John Markle, president; Edward C. Platt, first vice-president; Allan C. Bakewell, second vice-president; Charles P. Geddes, secretary; H. R. Swartz, treasurer and assistant secretary.

Syracuse, N. Y.—Jesse L. Hinds of the Crouse-Hinds Electric Company said lately that the firm is working all the men it has room for. Large orders are being filled for domestic and foreign trade. Encouraging reports come from the branch houses in the East and the outlook is good for a busy fall and winter for the manufacturers of electrical goods.

Walla Walla, Wash.—This place proposes to grant a franchise to an electrical company on condition of underground wires and a percentage of receipts to the city treasury.

POWER AND TRANSMISSION PLANTS.

Fairfield, Me.—Contractors have in hand plans for the erection of a new pulp mill in this village for the Somerset & Kennebec Company. The mill will be for the manufacture of pulp and electricity, the latter for use by the company in operating its railroad.

Vancouver, B. C.—A syndicate, headed by ex-Governor Mackintosh, has obtained control of the Slave Lake Power Company. The project contemplates the use of the water power of the falls on Slave River for the development of electricity for manufacturing purposes in this and other coast cities.

Weldon, N. C.—The Roanoke Navigation & Water Power Company will erect an electric transmission plant for power and lighting service.

AUTOMOBILES.

Cleveland, O.—A. W. Oppman, representing the company that wants to run a line of automobiles in the parks, says a five-year franchise will be accepted.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16⅜@16½c.; Lake, 16¾@16⅞c.; casting, 16½@16⅝c.

Directors of the St. Louis Transit Company have declared a quarterly dividend of 1¼ per cent. on the preferred stock.

The Milwaukee Street Railway has decided to spend $1,000,000 on its Milwaukee property within the next five years.

The Gas & Electric Company of Bergen County (N. J.) reports for September: Gross earnings, $20,730; operating expenses, $12,392; net earnings, $8,338.

The Manhattan Railway Company, of New York, has offered to lend six months' money at 5 per cent. on 20 per cent. industrial collateral.

The United Electric securities Company of Boston has declared a regular semi-annual dividend of 3½ per cent on its preferred stock, payable November 1 to stock of record October 21.

A dispatch from Chicago states that if the city council will give the Chicago Union Traction Company permission, all its North Side lines will be equipped with electricity. For this purpose the company is ready to spend $1,000,000.

The reports that an amalgamation of the Metropolitan Street Railway Company and the Manhattan Elevated Railway Company of New York City is seriously contemplated or that any change in their present relations are likely, is strenuously denied by authorities close to the Manhattan management. Inside interests deprecate these reports as misleading and are set afloat simply to affect the stock market.

President J. C. Osgood, of the Colorado Fuel & Iron Company, says that the Mountain Telegraph Company, just incorporated with $1,000,000 capital, is a step by his company to operate telegraph service between the mines and plant of the company. It is found to be more economical than the present arrangement with the Western Union Telegraph Company. The incorporation was necessary because the charter rights of the Colorado Fuel Company do not include building telegraph lines.

Directors of the Edison Electric Illuminating Company of Boston have elected the following officers: President, C. L. Edgar; vice-president, Walter C. Baylies; clerk, J. Otis Wardwell; treasurer, Raymond Apollonio. The directors have declared a regular quarterly dividend of 2 per cent., and an extra of 1 per cent, payable November 1. Transfer books closed October 13, and open November 2. The stockholders at their meeting on October 9 elected C. W. Amory and Robert Bacon to the board of directors, succeeding C. H. Coster and Jacob C. Rogers, both deceased.

The condensed balance sheet of the Edison Electric Illuminating Company of Brooklyn, as of September 1, 1900, shows: Assets—Property account, $5,565,536; license account, $945,000; merger account, comprising stocks and bonds in other companies, $2 613,750; stocks and bonds in other companies, $402,115; construction material and supplies, $129,150; accounts receivable, $233,237; bills receivable, $8,806; cash, $43,214; total, $9,970,808. Liabilities—Capital stock, $5,000,000; first mortgage, 5 per cent. gold bonds, $1,072,000; consolidated mortgage 4 per cent. gold bonds, $2 935,000; depreciation expense account, $200,000; bills payable; $275,000; accounts payable, $220,209; accrued interest on bonds, $223,383; profit and loss, $45,216; total, $9,970,808.

At a special meeting of Western Union Telegraph Company's stockholders on October 10, the issue of $20,000,000 4½ per cent. funding and real estate mortgage 50-year gold bonds was duly authorized. Of these bonds $10,000,000 were duly issued and the 6 per cent. and 7 per cent. bonds, due March 1 and May 1, 1900, were discharged and cancelled on the dates of their maturity. The annual report shows an increase during the year of 2,849 miles of poles, and an increase of 28,500 miles of wire; an increase of 615 offices, an increase of 1,769,626 messages transmitted, an average rate of 30.8 cents received for each message, and the average cost of each message 25.1 cents. E. H. Harriman and Charles Lockhart were elected directors in the places of Alonzo B. Cornell and C. P. Huntington, deceased. Other members of the present board were re-elected.

An official of the New England Electric Vehicle Company says: "The New England Transportation Company, originally had $2,250,000 in cash. About one-half of this has been invested in plant, real estate and the business generally, leaving a balance, which is in bank at 2 per cent. interest, of about $1,125,000. This would be equivalent to about $5 a share on the stock, or nearly $2 per share above the current market price of the stock, to say nothing of the company's plant, equipment, etc. For the year from October 1, 1899, to October 1, 1900, the receipts of the Company in Boston were about $100,000 and the expenses $290,000. This loss was due to the disadvantages under which the company had to operate during the first year. For the current month the Boston business shows a profit over expenses, and the net earnings during the twelve months ending October 1, 1901, should, I believe, be in the neigborhood of $50,000 or $60,000, at least."

It is said to be the purpose of the Massachusetts Electric Companies to ultimately consolidate its 40 different street railways into four operating companies. This is in a fair way for early accomplishment, says the Boston "News Bureau." Within a short time all the lines north of Boston will be consolidated with either the Lynn & Boston or the Lowell, Lawrence & Haverhill. To the south of Boston the West Roxbury & Roslindale Company will eventually control all the roads. At present there are three operating roads on the South Shore; the West Roxbury line, Brockton and Taunton roads, or there will be, when the South Shore & Boston is consolidated with the Brockton Company and the Globe Street Railway of Fall River is consolidated with the Taunton Company. Petitions for such consolidations are now before the railroad commissioners. The three Rhode Island properties will be consolidated into the Newport & Fall River Street Railway Company. These consolidations will greatly facilitate the operation of the properties.

EDITORIAL NOTES.

Electric Haulage for Canals.

In view of the fact that it will probably not be many years before the principal canals or waterways in this country will be permanently provided with electric systems for towing canal-boats what is being done along this line abroad should prove interesting.

The various electric schemes so far suggested for moving canal-boats may be briefly, and in a general way, divided into three systems: That of moving a canal-boat by means of a portable motor outfit placed on the boat itself; that of drawing one or more boats through a canal by means of an ærial carriage supported on cables running along the bank, and lastly, that system in which an electric tractor or locomotive running along the bank itself is made use of. The latter method would seem to be the most popular just at present and numerous experiments are being made, especially in Germany and France. About a year ago such a system of canal towage, then recently installed on a waterway between Dortmund and Emshäfen in Germany, was described in these columns, while not long ago electric tractors were given a trial on a short length of the Finow Canal, which forms a portion of the waterway between Berlin and Stettin. These experiments were made on behalf of the Prussian Government and are described by the Consul General of the United States at Frankfort.

The crafts that run on the canal are in the the main barges, some 132 feet long by 115 feet 6 inches beam, carrying 150 to 175 tons. There are also a few steam barges employed, which carry about 150 tons and can tow a second barge. The traffic to Berlin is much heavier than toward Stettin, and as a consequence thee-fourths of the barges return light from the metropolis. Traction is generally effected by horses, there being a towpath on each bank, but on the down journey man traction is not infrequently relied on. In any case the speed is low, and, including stops, does not average more than 1¼ miles per hour.

The section of canal used for the experiments was selected owing to its physical difficulties, presenting, as it does, several curves, in one of which with only 328 feet radius the waterway is spanned by a railway bridge. The line laid down for the towing engine was of 1 meter (3.28 feet) gauge, the outer rail weighing 18.2 pounds per yard, while the inner, which was fixed on the inner edge of the towpath, weighed 9.1 pounds per yard. These rails, which were of the flange type, were laid partly on sleepers ballasted with gravel and partly on blocks of concrete, weighing 220 pounds each in the case of the heavier principal rail, and half this in case of the other rail. This arrangement costs more per mile than the sleepers, but has been found less expensive to maintain. Though no wharf actually existed on the length of canal experimented on, the arrangements necessary were fully tested. At one point the line was raised to a height of 9 feet 6 inches above the level of the towpath, being carried on posts and brackets. The carrying posts were 12 inches in diameter, and were spaced at 18 feet 8 inches. A cap piece spanned the gap between the posts, and the principal rail was laid directly on this cap piece, while the other was carried by a stringer supported at each post on brackets.

The conductor for the current was supported on pine posts 23 feet long, located 35 to 44 yards apart. It consisted of 8-millimeter wire, carried by porcelain insulators. The principal rail served as conductor for the return current. The source of power was a 15 horse-power portable engine, driving a 9 kilowatt dynamo, and a large storage battery was also provided. The extreme dimensions of the towing locomotive were 6 feet 10 inches in length by 4 feet 10 inches wide. Its total weight was 2 tons; but the motor was so placed that only one-fifth of this total came on the accessory rail The motor provided was much more powerful than necessary for the work in hand, as it was capable of working at the rate of 14 to 15 horsepower. Since, however, these experiments were merely preliminary ones, intended to test the possibilities of electric traction for large barges, the excess power was supplied intentionally, and the resistance requisite to call forth the full powers of the motors was in some of the experiments provided by rafts. These experiments showed the system to be capable of meeting all needs, working, as it did, with safety and economy.

Another system referred to briefly in our last issue was recently given a trial between Béthune and L'Escaut in France, a distance of 47 miles. In this case the tractive apparatus consisted of electric haulers, each weighing two tons. They are mounted upon four wheels, of which two are driven. The length of a hauler is 14 feet and the breadth 4½ feet. In this sys-

Digitized by Google

tem current at 500 volts is derived in the ordinary manner from an overhead conductor.

The advantage of electric haulage over that of steam or animal is forcibly demonstrated when it is stated that with the latter it was shown to cost .213 cent to haul one kilometric ton, whereas, when an electric hauler is made use of, this figure is reduced to .142 cent.

If the figures given are correct, and there would seem to be no valid reason for doubting it, it would certainly pay to install at as early a date as possible permanent electric haulage systems along the various canals in this country.

* * *

Motor Power Schemes Abroad. There are at the present time a number of large water-power schemes in contemplation or in course of construction. One of these is at Niagara Falls, a description of which will be found in last week's ELECTRICITY. The other schemes we refer to are in Sweden and Switzerland. At Vestmanland in the former country a power plant has been in course of construction which, when completed and in running order, will deliver current for lighting and manufacturing to Vesteras, a town 14 miles distant. The power for operating the turbines, of which there are six, is derived from the Kolbock River. The latter has been dammed, and from its north side the water passes to the power-house through a canal 1,130 feet long, 23 feet broad and 8 feet in depth. The water is led to the turbines through three pipes 8 feet in diameter. The current from the six generators is collected and conveyed to 18 transformers where the voltage is raised from 800 to 14,000. After passing over the three copper conductors to the town the tension is again reduced through the same number and size of transformers and distributed to the various consumers.

The Swiss scheme is a most extensive one. It is described in detail in a recent issue of the "Bulletin" of the Société des Ingénieurs Civils de France, and has been abstracted and translated by the London "Electrical Engineer." The scheme, or, more properly speaking, schemes, consist in utilizing the waters of the river Rhone. From Pyromont to Fort de l'Ecluse the Rhone falls rapidly through a series of gorges and drops 210 feet in a distance of 12½ miles. Attention is called to the fact that the Lake of Geneva acts as a reservoir in regulating the flow, and that the minimum amount of water passing down the river is at least 5,250 cubic feet per second. From this data it is computed that the minimum effective horse-power which can be obtained in the driest months is 100,000, while for nine or ten months in the year one could depend on getting at least 200,000 hp. Up to the present the only quantity used amounts to 10,000 hp., which is obtained by an Anglo-Swiss company, but there are three schemes on foot organized by French concerns, which only wait for the formal sanction of the authorities before commencing work.

The first of these schemes, which would have its works about 2½ miles from Bellegarde, would, when completed, be able to provide 25,000 hp. even in the winter months when the river is lowest. The next scheme takes its name from the Joucle du Rhone, and would develop 30,000 hp. from a fall about 90 feet. In the third scheme the fall utilized is above Bellegarde, and here again 30,000 hp. is expected to be obtained. The horse-power which it is proposed to develop at these three power-stations would be largely used for electro-chemical and electro-metallurgical purposes, but current would also be transmitted to industrial centers within a radius of 100 miles. The article states that the various promoters think that $10 per horse-power hour per annum will repay for the cost of the works, and this will be about one-tenth of the cost of the horse-power per annum in the district when obtained from coal.

From the foregoing it will be seen that this country is not the only one in which mammoth water-power enterprises are being agitated and constructed.

* * *

The American Street Railway Convention. The Nineteenth Annual Meeting of the American Street Railway Association, recently held in Kansas City, Mo., proved satisfactory in every way. The papers presented, though few in number, contained an unusual amount of useful and interesting information, especially the one entitled "Double Truck Cars: How to Construct and Equip Them to Obtain Maximum Efficiency with Minimum Cost of Maintenance." This paper, which was read by Mr. N. H. Heft, brought out a very lengthy and valuable discussion, which we hope to find space for in a subsequent issue.

As usual, there was a very large number of material men on hand, and, as a result, the exhibition of street railway appliances was most interesting.

The social features were everything that could be desired, opportunity being afforded the members of enjoying a theater party, trolley ride and the usual banquet.

The proceedings of the Convention in detail will be found elsewhere in this issue.

* * *

American Trade Interests Abroad. It has been aptly said by someone that we are living in a commercial age; all the energies of the human race are focused on the goal - commerce. Our country has been called the workshop of the world.

A solution for many of the complex problems that are causing anxious thought to those who have the Nation's best welfare at heart may be found in the expansion of American trade. Every year there is an increase in our production for exportation greater than that for our home consumption. And yet it is safe to say that our export trade is only in its infancy. To-day we rank as the third commercial nation, and this without any special effort being made to so hold ourselves. The growth has been very gradual and natural, foreign countries being the solicitors rather than the solicited. Our manufacturers are only just beginning to realize the immensity of the field for export trade that is awaiting systematic effort to reach it.

There are many obstacles to be overcome before we will be able to throw the whole weight of our resources on the markets of the world. Without a thorough study of the needs of foreign peoples our manufacturers will ever find export trade to be uphill work. Every year it becomes more apparent how much we stand in need of specially trained men to represent American trade interests abroad. Only such men can obtain satisfactory results after they have received an education preparatory to such work. Commercial and industrial education is one of the signs of the times, and the quicker American manufacturers grasp this point the better it will be for the export trade.

What is needed, for example, is to apply the admirably arranged commercial and technical school system of Germany to our own methods. Having made this our own we would be in a position to take an interesting part in the irresistible aggression in the struggle for foreign markets.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

GENERAL Greely has lately received a report from Manila saying that sixty miles of cable for use in the Philippines have arrived, and will enable the signal corps to complete a number of telegraph lines in the islands.

THE structural work on the new electric tramway for the city of Glasgow, Scotland, which the Riter & Conley Manufacturing Company of Pittsburg, Pa., has been building for the past year, is so nearly completed that the company expects to order the men at work there to return home in about two weeks. The new line covers a number of the streets of Glasgow and is built almost exclusively of American steel.

ACCORDING to news recently received from Paris the Autombile Club de France has decided in conjunction with the German Club to hold a race from Paris to Berlin early next year. Emperor William has promised prizes to the value of $10,000.

MR. C. W. SQUIER, who has been employed for some years in the General Electric Works at Schenectady, N. Y., has accepted a position with the Sprague Electric Company at Bloomfield, N. J., and will have charge of the controller department.

A HIGHLY ingenious apparatus for discharging an electric line of high pressure electrostatic charges, or of those due to lightning, was tested with satisfactory results on several trolley lines during the past summer. It consists simply of a glass tube about a foot long filled with small shot. The shot is treated chemically before use to give it a light coating of lead carbonate, which is an indifferent conductor. This tube is provided with metallic ends and is connected in series, with a spark-gap between the line to be protected and the ground. To the rapid oscillating current of high pressure induced on the line by lightning the tube of shot offers practically no resistance and the discharge goes to earth. To the heavy trolley current, which at once begins to follow along the path made by the lightning discharge, the resistance of the shot is enormous and the current is at once broken. This action is very similar to that of the coherer, or tube of metallic filings, used in wireless telegraphy.

THE advent of electricity and the general advancement of science, says H. G. Gardner in the Washington, D. C., "Star," has brought new work to the bureau of weights and measures. It has also emphasized the need of adequate legislation under the constitutional power to provide the country with uniform standards. All over the land people are paying for electric light, and yet they have no standard by which to measure it or to guage the size

Digitized by Google

of their bills except the say so of the company which furnishes it. There is no legal standard of measure and the "ohm," which is borrowed from Germany, may be a big or a little ohm as it suits the company to make it. There is no standard "candle-power," and there is no way for a customer to know whether his lamp is of a certain brilliancy or not. The same principle applies to the scale of electric power for the running of machinery. The United States has bought some testing apparatus for measuring volts and ohms from Germany, which is the source of all the best scientific equipment, but no effort has been made to furnish the States. The appropriation for this purpose has been entirely inadequate. The question of establishing an American standardizing bureau will come before Congress at next winter's session. A bill was introduced last December and was favorably reported by the House committee having it in charge. The Senate committee on commerce has not yet given it consideration. It is proposed to create a bureau with authority to undertake all functions contemplated by the clause in the Constitution relative to "fixing the standard of weights and measures."

MAIL advices from Buenos Ayres state that the use of electric motor cars in the Argentine capital is developing rapidly. Not only heavy delivery wagons, but also luxurious carriages operated by electricity are frequently to be met with on the streets of that city. The roads are gradually being improved, and a touring club has been formed with a view to watching over the interests of automobilism. One of the first resolutions of this club, the members of which comprise many merchants and influential amateurs, has been to establish throughout all the provinces of the republic, roads specially reserved for light motor cars and bicycles. These roads already radiate from Buenos Ayres for a distance of from 60 to 70 miles, and the work will be continued till a netword of similar roads exist all over the country.

TROLLEY cars, like other things, will wear out, and in Brooklyn, when they reach this condition, after being divested of everything that can be made use of, they are then cremated. A thousand and more have already been destroyed in this manner; scores of others will meet the same fate. The foreman of this odd wrecking gang sets the match to them himself, piling up in each car cotton-waste and fragments of wood, pouring kerosene about liberally.

ON the shelves at the Patent Office at Washington, D. C., are scores of modest models of inventions the world could not now well do without. The greatest inventions have been but the crude beginning of some idea subsequently perfected. The models seem to partake of the same crudity. Take the telephone, for instance. In the Patent Office are two cones of wood with membraneous ends and a confusing tangle of metal and wire. Each of the cones could be hidden in one's hand. Yet they are the beginning of an idea that has been perfected to the elaborate instrument of today, out of which millions have been made, and by the use of which continents are bridged. No one at first glance would associate these insignificant bits of wood and metal with the telephone of to-day. Of scarcely less commercial importance are the arc and incandescent lights. The arc-light has undergone little change in general form since it was patented by Colner and Baker on May 18, 1858. There have been wonderful changes in its mechanism, but the hour-glass form of the first model is still preserved. With the incandescent light it is different. There is not the slightest resemblance between the first model and the bulb light of to-day.

CAPTAIN SIGSBEE, Chief of the Naval Bureau of Intelligence, has received from Lieutenant Louis R. de Steiguer, U. S. N., an interesting report on the use of electricity on board naval vessels. It is shown that within a few years the motor has supplanted all else in operating the auxiliary machinery of war vessels of all classes, and it is believed that before many years a very elaborate system will have been invented whereby electricity will do almost everything required on a battle-ship. The rereport is made from observations and inspection of the vessels of the United States and foreign navies.

EAST CLEVELAND, O., will soon have an automatic water-pumping system, driven by electric motors. Current will be supplied from Cleveland, and the pumps will be run without any further attention than an occasional oiling. The water, taken from the 10-inch Cleveland main, will be forced up the hill back of the village into a large steel reservoir. The height of the reservoir is sufficient, not only to give the house pressure required, but will be enough for fire-plugs, thus enabling the local fire companies to dispense entirely with their old fire-engines.

A NOVEL electric sign with over fous thousand lights, and which cost about $10,000, is located on the Detroit River at Walkerville, Mich.

C. J. FIELD, chairman of the technical committee of the Automobile Club of America, has announced the programme of track tests for automobiles during the coming automobile show in Madison Square Garden of this city, from November 3 to 10. All of the events, except those for Friday, November 9, will be open only to the vehicles in the exhibit. The list of track tests includes, among other things, a brake contest for electric vehicles, an obstacle contest for electric vehicles, and similar tests for gasoline and steam automobiles. In addition to the exhibition of new machines, there will be a number of foreign carriages shown by members of the Automobile Club of America, under whose auspices the show will be given. A. C. Bostwick will exhibit his new French record-holder, of twenty-four horse power; D. W. Bishop will show his sixteen horse power French carriage of the same make; S. T. Davis, Jr., a steam-racing carriage; A. L. Riker, an electric racing carriage, and Alex Winton, a gasoline racing carriage. The firms exhibiting vehicles will have stored at the east end of the Garden between fifty and seventy-five carriages, which will be run on the track, and it is the intention of the management to have from twenty to twenty-five carriages moving on the track at all times during the show, except when competitions are on.

THE Sprague Electric Company has secured the contract for ventilating the beautiful new Grand Central Depot, New York City. The ventilating fans, ranging in size from 18 to 60 inches, will be operated by the well-known Lundell electric motors.

American Street Railway Association Convention.

Synopsis of the Proceedings at Kansas City —Walton H. Holmes Elected President— The Next Convention to be Held in New York City—Meetings Hereafter to be Limited to Three Days Instead of Four.

The Nineteenth Annual Meeting of the American Street Railway Association was called to order by President John M. Roach at the Convention Hall, Kansas City, Mo., at 11:15 A.M. October 16. The President said:

Gentlemen, you will please come to order. The first business of the session this morning will be an address of welcome. We have a distinguished citizen of this city with us this morning and he will extend a welcome to you. I take great pleasure in introducing to you his honor, James A. Reed, Mayor of Kansas City. (Applause.)

Mayor Reed then delivered the address of welcome, and, among other things, said:

Mr. President and Gentlemen: I do not know whether I can make you hear me this morning or not. My voice, which usually is as soft and as musical as the notes of a flute wafted over moonlit waters, has been laid on the altar of my country to such an extent in the last few days that I imagine it bears a distinct resemblance to the inharmonious blending of the sounds of a cracked fiddle and the roar of a buzz-saw. If I can make you hear, and say something to make you feel at home in this city, I shall be delighted. I esteem it, Mr. President and gentlemen, a great honor to address this body of distinguished gentlemen, which possibly resembles the funeral of Abel, which was small but select; none but the first families were present. (Laughter.) I trust that your meeting here in this roof garden is not being held under that part of the Scriptures which states that "The wicked dwell in high places." (Laughter.) In the little I have to say to you, gentlemen, I shall not bore you with a speech, because I do not know what purpose a speech serves on an occasion of this kind. The old Egyptians had a custom, so it is related, when they had a feast and everybody was feeling hilarious and good-natured—they had a pleasant custom of passing around a skull and saying to each of the guests "Remember you are mortal, remember you are mortal." I apprehend I was brought here to represent the skull and cross-bones of this occasion. You are here to transact important business, having important objects in view, and it is not a time for speech-making. It is a time when you desire to deliberate and get to business. I want to say on behalf of this city that Kansas City, as much as any other city in the world, welcomes to her midst the representative business men of all other cities. We believe out here in the West that it takes capital, brains and courage to build cities. We know out here in the West that if capital comes to us it must come because it expects a fair remuneration; and I want to call your attention, gentlemen, to the fact that you are in Missouri, and, notwithstanding the fact that all of the States that surround us, in times past, in those troublous times, when there were hard financial conditions existing, while every other State in the Union, almost—I will qualify it by saying when nearly all the Western States—placed upon their statute books laws aimed at the destruc-

Digitized by Google

tion of the wealth of financial institutions, there never has been a syllable, line or sentence of what we commonly denominate crank legislation placed upon the statute books of Missouri. (Applause.) I need not extend to you the liberty of this city. That old phrase died years ago, and then I never saw a lot of street car magnates in my life that needed the liberties of a city; they generally know how to get them (laughter); but you are welcome here among us, and I know you will be made to feel at home, because I know the Messrs. Holmes, and their associates in business here will make you feel welcome and at home. You may read something in the papers here of police outrages, but if, perchance, you lose your way, for that is all would ever happen to so distinguished a body of gentlemen as you are—if perchance you do lose your way, I guarantee you that some good police-officer, like a good Samaritan, will conduct you to your hotel in peace and with due dignity, and, if necessary, will take you up the back way.

President Roach—Mr. Mayor, on behalf of the Association, I desire to thank you for your eloquent words of welcome spoken to us, and also to give you my personal thanks.

The first business at this meeting is the calling of the roll. If it is the pleasure of the meeting, instead of taking time to call the roll, the official registration of the Secretary will be deemed the calling of the roll. That has been the custom in the past, and will be considered as applying at this time, if there is no objection. We now extend an invitation to those companies represented at this meeting which do not belong to our Association to join us, if there be any here of that class: or if the representatives of such companies have not time to do this at present they can do so later by applying to Secretary Penington.

The next business before the meeting is the address of the President.

President Roach then read the following address:

The President's Address.

Gentlemen—It gives me great pleasure to meet with you in this magnificent Western city. I have every assurance that nothing will be left undone to make our visit most pleasant and profitable. There is a breadth of character and freedom, of personality in this young metropolis of the plains which peculiarly appeals to the business man who has large interests entrusted to his care, and I believe the members of the Association will show their appreciation of the many pleasant things provided for their entertainment while in this community. When this Nineteenth Annual Convention of the American Street Railway Association shall have finished its labors, I am sure that I may safely say to Mayor Reed that none of you will have regretted the hospitality of the people of Kansas City, so graciously extended by him.

I see before me representative men from all the leading cities of this country. To your hands is entrusted street railway investments aggregating hundreds of millions of dollars and the welfare of over a million persons. From the single track, one-horse car of forty years ago, the business in which you are engaged has grown to a magnificence where nearly all fields of human endeavor are called upon to perfect its equipment or aid in its management. It has outgrown ridicule and financial instability and in the rapid whirl of events has built cities, enriched its promoters and made possible a freer, healthier and happier life for its patrons. Each day the street car is entering more and more into the business life and pleasures of the community, and each day its benefits are becoming more apparent to the general public.

The street railways of America now represent the enormous investment in bonds and stocks of $1,800,000,000 upon which investors are receiving annually over $70,000,000 in dividends and interest. Salaries and wages amounting to $250,000,000 a year are distributed among the 300,000 employes necessary to equip, operate and manage this great industry, repair its 20,000 miles of track, handle its 60,000 cars and meet the ever-pressing demand for improvement. Directly and indirectly over 1,200,000 persons depend on the traction interests of America for their livelihood.

An industry of such proportions penetrates and more or less affects all other enterprises in the country which sustains it. Nine-tenths of the business men and women of the United States look to the management of street railway companies to furnish them with swift, comfortable and safe transportation to and from business. Still a greater per cent. of pleasure seekers demand and receive from the same management to and from theater, casino, park and suburb, transportation of such elegance of equipment and efficiency in service as to satisfy the most exacting. It has required heroism and patience on the part of street railway men, with so little friction, to meet the demand of a critical patronage in so excellent a manner as is being accomplished by them at the present time.

On all sides, we hear the cry of improvement and in every direction we hear the sound of the busy car shop as it responds to the demand for more modern equipment. The public is becoming more exacting and there is need for the most perfect knowledge and the widest experience to successfully cope with the ever-changing situations which confront the street railway manager. Street railway companies have frequently, at great cost, increased their miles of tracks and added to an extensive equipment, primarily for the sole purpose of accommodating the public, by penetrating into outlying districts, unwarranted by additional business to be acquired in such territory. This policy has proved wise in nearly every instance. It requires considerable pluck on the part of a company to back a temporary loss in order to please its patrons. Those companies which have pursued such a course have generally been rewarded by more liberality on the part of municipalities, more good nature and praise from patrons and an early increase in the new districts acquired, which soon brought those lines to a paying basis.

In thus catering to the wishes of the public the street railway industry of the United States has been brought to a high standard of excellence and has kept safely in advance of traffic. The aggregate of miles of track has grown from a few hundred miles of single track, confined mainly to business centers, to many thousands of miles of thoroughly equipped double tracks, which have brought the country districts within quick and active touch with the larger cities. Such energy and management must and will be appreciated and fairly treated by the communities benefited.

It may be declared that corporations are without soul, but it cannot truthfully be said that street railway corporations are lacking in good sense or business principles. False economic doctrines yield to and flee before rapid development and prosperity. A well-equipped street railway with modern service, which seeks to oblige the people, operated in any community, will develop the best resources thereof, and bring prosperity to its people with such rapidity as to utterly confuse and put to flight all false economic doctrines.

Newspapers, reviews, magazines, periodicals and journals of this country, indeed of many parts of the world, are entitled to the thanks of this Association for the fair and generous treatment accorded in their columns to the street railway men and their interests during the year. It is the province of these publications to exploit the great industries of the land. If upon one day we are able to congratulate ourselves upon their unstinted praise, we should patiently bear the publicity of our faults, if any there be, in the next issue.

The last year has been a period of notable activity and healthy progress, with but few disturbances of a serious nature. The managers of large street railway properties should shape their policy toward their employes, and the public, so that disturbances between employer and employe will be entirely eliminated from their history. The management of the great corporations of the country can best retain the adherence and loyalty of employes by adopting toward them a policy at all times just, and at the same time courteous, kind and conciliatory. The good will of your employes and of your patrons will be found an asset of great value in the days of trouble and most desirable at all times.

A business so widespread in its usefulness, holding and judiciously employing as it does so great a portion of the capital of the country, and so essential to the best interests and prosperity of the trade centers, should, and I believe in good time will, possess the very necessary good will and hearty support of the municipalities it so faithfully serves. Our interests and those of the public are inseparable interwoven and naturally harmonious. If such interests become strained, therefore, it should become one of the leading features of our Association to suggest a uniform policy for street railway companies, of so broad a gauge that the mutuality of the best interests of the public and of the company shall be as apparent to the people as to the street railway managers themselves.

I take pride in announcing that the condition of your Association, both as to membership and finances, is improving each year. I wish to urge you to make this gathering of use to our Association and of importance to the street railway industry. This may be accomplished by a full attendance upon and participation in the business meetings. The Executive Committee has selected members who have prepared papers on important subjects and I urge upon you the advisability of entering into full discussions and analysis of these subjects so that a clear understanding of all questions presented may be carried home with you. I also urge the Association to show appreciation for our friends, the supply men, who have produced for this annual meeting their splendid exhibit.

Allow me to request your hearty support in the work of the Accountants' Association, which meets in annual convention here at this time. Its work is of great importance and is worthy of your most serious consideration.

To the Secretary and members of the Executive Committee our thanks are due for the satisfactory manner in which they have assisted in

Digitized by Google

conducting the affairs of this Association. Personally their efforts have been highly appreciated.

The honor of having acted as your President for the last year has been most gratifying to me and shall ever remain one of the pleasant recollections of my life as a street railway man. For my successor, I bespeak the same courtesy and cordial co-operation which it has been my good fortune to enjoy. Gentlemen, I thank you.

The President—The next business in order is the report of the Executive Committee.

The report was then read by Secretary Penington.

The President—Gentlemen, you have heard the report of the Executive Committee. What is your pleasure?

Mr. Dyer, Augusta—I move that the report of the Executive Committee be adopted as read.

Motion carried.

Mr. McCulloch, Chicago—Mr. President and Gentlemen: I think it is due to Mr. Durbin to state why he resigned his membership of the Executive Committee. Those of us who know him know he is not in the habit of shirking responsibilities. He has gone out of the street railway business

The Secretary—Mr. Durbin has gone out of the street railway business, and did not think he ought to continue to hold his office as a member of the Executive Committee.

The President—We will now hear the report of the Secretary and Treasurer.

The Secretary then read the report, which showed the receipts of the Association up to October 10, 1900, including $5,658.87 cash in bank, to be $12,223.42, and expenses up to the same date amounting to $5,222.67, leaving a balance in the bank of $7,000.75.

The President—Gentlemen, what action will you take upon the report of the Secretary and Treasurer?

Mr. Graham, Quincy—I move that the report be received and placed on file.

Motion carried.

The President—The next business before the Convention will be the reading of a paper by Mr. Daniel B. Holmes, counsel of the Metropolitan Street Railway Company, Kansas City, Mo., on the subject "Consolidation of Street Railways and its Effect Upon the Public."

The paper was then read by Mr. Holmes, after which the President said:

Gentlemen, you have heard the paper read by Mr. Holmes. What action will you take in regard to it?

Mr. Rigg, Reading—I move that it be received and spread upon the minutes, and that we tender Mr. Holmes a vote of thanks for the interesting paper.

Motion carried.

The President—Mr. Holmes, I desire on behalf of the Association and personally to thank you for the very able and distinct manner in which you treated the subject embraced in your paper.

Mr. Holmes—I appreciate the compliment very much.

The President—Is there any gentleman present who would like to discuss the paper just read? We would be glad if anyone has anything to say to hear from him. I imagine the gentleman has treated the matter so comprehensively and in such a diplomatic manner there is very little additional that can be said. It is natural, under such circumstances, as he seems to have covered the ground so fully, for us to have passed this vote of thanks to him. I desire to state that, upon adjournment of this meeting, we shall hold a meeting of the Executive Committee.

After the announcement by the Secretary that there would be a reception at the Midland Hotel that evening the meeting adjourned.

WEDNESDAY—OCTOBER 17.

President Roach called the meeting to order at 10:50 A. M.

The President—For reasons unnecessary to explain at this time, we have changed the order of business somewhat. The names of the nominating committee have been selected, and the Secretary will now read them. This committee will also recommend to the Association a place for our next meeting.

The Secretary read the names of the commiteee on nominations as follows: Chairman, John A. Rigg, Reading, Pa.; E. C. Foster, Lynn. Mass.; E. G. Connette, Syracuse, N. Y.; D. B. Dyer, Augusta, Ga., and Robert McCulloch, Chicago, Ill.

The President—I would say to the gentlemen who have any idea of asking the Association to hold its next meeting in their city, that they can see Mr. Rigg, the chairman of the committee on nominations, any time at their convenience. Mr. Rigg will appoint a time and place for the meeting of the committee.

Secretary Penington—Mr. President, I will state that I have received invitations from the Mayor of Cincinnati, the President of the Cincinnati League, and from President Kilgour, of the Cincinnati Street Railway Company, asking us to hold the next Convention in that city. I will turn these invitations over to Mr. Rigg, chairman of the committee.

The President—The next order of business is the reading of papers. The first paper on the programme this morning is entitled "A Comparison of the Various Systems of Electrical Distribution for Street Railways," by Mr. C.F. Bancroft, electrical engineer of the Massachusetts Electric Companies, Boston. Mr. Bancroft is not in attendance at the meeting, and it will devolve upon the Secretary to read the paper.

The Secretary then read the paper, which elicited a discussion participated in by Messrs. Foster, Connette, Dyer and Wason.

The President—The next regular order of business is the reading of the paper on "Painting, Repainting and Maintenance of Car Bodies," by Mr. F. T. C. Brydges, superintendent of car shops, Chicago Union Traction Company, Chicago, Ill.

In the absence of the author the paper was read by the Secretary. A short discussion followed in which Messrs. Harrington and Foster took part.

The Secretary then announced that there would be a theater party in the evening at Coates Theater, after which the meeting adjourned to Thursday morning.

THURSDAY—OCTOBER 18.

The meeting was called to order by President Roach at 11:10 A.M.

The President—Gentlemen, we will proceed to the regular order of business this morning. The paper on the programme is entitled "Double Truck Cars: How to Construct and Equip Them to Obtain Maximum Efficiency with Minimum Cost of Maintenance." This paper is by Mr. N. H. Heft, president of the Meriden Street Railway Company, Meriden, Conn.

Mr. Heft then read the paper, which proved to be most interesting and which elicited a lengthy discussion, participated in by Messrs. Foster, Chamberlain, Heft, Harrington, Wason, Beggs, Vreeland and others.

President Roach—Gentlemen, the next order before the Convention is the report of the committee on nominations.

Mr. Rigg, chairman of the committee on nominations, then presented the following report:

Gentlemen—Your committee on nominations respectfully reports that it recommends New York City as its next place of meeting, and also recommends the following gentlemen for officers of the Association for the ensuing year.

For President—Walton H. Holmes, president Metropolitan Street Railway Company, Kansas City, Mo.

For Vice-President—Herbert H. Vreeland, president Metropolitan Street Railway Company, New York.

For Second Vice-President—N. H. Heft, president Meriden Electric Railroad Company, Meriden, Conn.

For Third Vice-President—J. B. McClary, general manager Birmingham Street Railway Company, Birmingham, Ala.

For Secretary and Treasurer—T. C. Penington, treasurer Chicago City Railway Company, Chicago, Ill.

Executive Committee—The President, Vice-Presidents, and John M. Roach, Chicago; F. L. Fuller, Wilkes-Barre, Pa.; George W. Baumhoff, St. Louis, Mo.; John R. Graham, Quincy, Mass., and John Harris, Cincinnati, O.

The following resolution was unanimously passed by the committee:

Resolved, That the next meeting of the American Street Railway Association be limited to three days instead of four, and that the day set apart for the personal examination, by members, of the supply men's exhibit, be the middle day of the interval.

President Roach—Gentlemen: The election of officers is by ballot, and I will select Mr. McCulloch of Chicago and Mr. Beggs of Milwaukee, to act as tellers.

Mr. Bean, St. Joseph—I move that the Secretary be authorized to cast the unanimous ballot of the meeting for the gentlemen nominated.

Motion carried.

The Secretary duly cast the ballot and the President declared the gentlemen nominated to be duly elected as officers of the Association for the ensuing year.

President Roach—There will be no further meeting of the Association, but we will adjourn until to-morrow night at 7 o'clock to meet at the Coates House for the annual dinner.

I desire to thank the members of this Association for their kind consideration while I have been your President, and if there is anything I can do at any time to help the Association, I will be pleased to have you call upon me while here and at home. (Applause).

Mr. Heft—I move that the thanks of the members of this Association be tendered to our able and genial President and the other officers of the Association, for the able manner in which they have conducted the affairs of the Association during the past year.

The motion was carried by a rising vote.

Mr. Vreeland—Before we adjourn, it would seem right along this line that it would be proper for this Association to express its appreciation of the entertainment that has been extended to the members of this Association by the Metropolitan Street Railway Company of Kansas City, and by the leading citizens of Kansas City, whose generosity has never been paralleled in my history in connection with associations of this character.

The motion was put and unanimously carried.

The meeting then adjourned.

MEASUREMENT OF THE RESISTANCE OF CABLES.*

BY ARTHUR C. HEAP.

To conform to the requirements of recent specifications for electric light cables, it has become necessary for manufacturers to provide themselves with instruments which shall be capable of measuring the resistance not only of the samples of copper of which the cable is made, but also of the finished cable.

The measurement of the resistance of samples, where the copper is drawn into wire of suitable section, and where any desired length may be taken, can easily be done on the Wheatstone bridge; but when the resistances of short lengths of large section cable have to be measured, it is necessary to resort to one of the difference of potential methods. At the same time the instruments used must be accurate, direct reading, and quickly handled, and the connections must be such that they can easily be followed by the consulting engineer or his assistant, who may not be familiar with the particular test room in which he is working. Of these potential methods, the simplest is probably that in which the direct-reading potentiometer is used.

In England the low resistance potentiometer is, on account of its greater rapidity of working, almost universally employed.

The test consists in balancing the fall of potential produced by a current passing in a suitable length l (Fig. 1), of a slide wire, R, R, R,

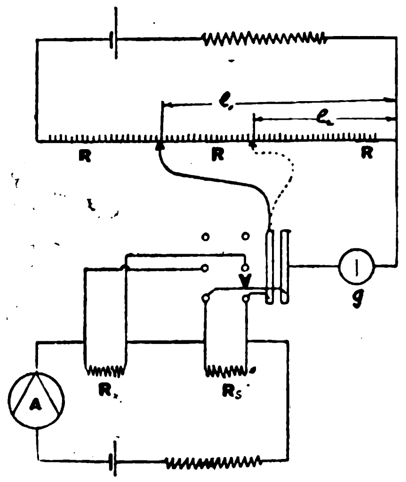

FIG. 1.

whose resistance per unit length has been accurately adjusted, against the fall of potential over a standard resistance, R_s of suitable value, the unknown resistance, R_x and the standard, R_s being connected in series in a circuit in which a constant current is maintained; the fall of potential over the unknown resistance is then, by moving the switch V, substituted for that over the standard, and the position, l_2, at which balance is obtained on the slide wire noted. The resistances are then directly proportional to the lengths, l_1 and l_2, of slide wire employed; that is,

$$R_x = R_s \times \frac{l_2}{l_1}.$$

The instruments necessary are, therefore, a potentiometer, in which the adjusted slide wire is conveniently arranged, a set of standard resistances, a sensitive low resistance D'Arsonval galvanometer, a secondary cell for maintaining a constant current in the slide wire, another for maintaining a constant current in the standard resistance circuit, a regulating resistance and ammeter for this circuit. Fig. 1 is a diagram illustrating the method; Figs 2, and 3 a particular form of potentiometer and standard resistance brought out by Messrs. Elliott Bros. In Figs. 1 and 2, R, R, R, is the adjusted slide wire, which is about 450 inches long, having a resistance of about 35ω, divided into 150 parts each of approximately 3 inches, by having small copper tags silver soldered to the wire; 149 of these are fixed by means of screws passing through holes in the ends of the copper tags to an ebonite ring, S, as shown, a second ebonite ring, T, carrying a contact

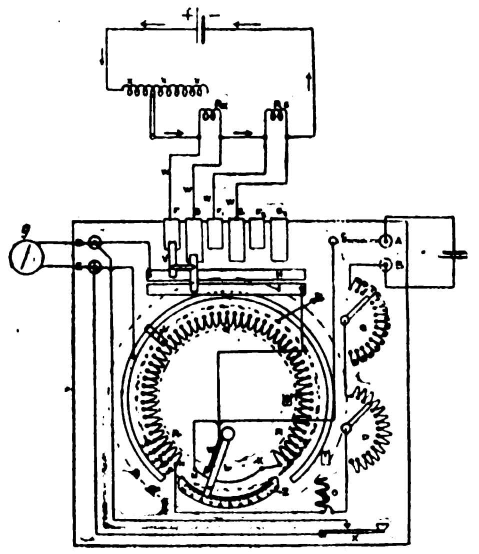

FIG. 2.

tongue, J, turns concentrically round the first ring on balls running in a ball race, U, cut between the two rings. This tongue, J, as it moves round makes contact on the heads of the screws fixing the slide wire; the outer ring T, is engraved with figures from 0—149 in such a manner that as they appear at a window, they indicate the number of the stud on which the tongue, J, is making contact. The 150th portion appears on the top of the instrument at MK, and is the portion on which the key, W, attached to the lever, L, makes contact; this lever travels over a graduated scale, Z, which indicates the position of the key.

The manufacturer's adjustment consists in making each of the 150 portions of the slide wire accurately equal to one another, and in calibrating the scale over which the key travels. O, P, Q, are resistances in series with the slide wire, R, R, R, and have no accurate ohmic values, but are such that O being the slow adjustment of approximately 1 ohm, the resistance between each two studs of P is about 0.95 ohm, and the resistance between each stud of Q is about 13.25 ohms, that is, they are overlapping rheostats, having a total resistance of about 188ω; G is a delicate d'Arsonval galvanometer, having a resistance of about 50 ohms; V is a multiple switch, having contacts F, G, F_1, G_1, etc., by means of which six different quantities can be compared; C is a fuse to protect the slide wire, and X is a shunt key to reduce the sensibility of the galvanometer.

As the range of resistances to be measured is wide, varying from 0.2 ohm for samples down to .00528 ohm, which is approximately the resistance of ¼ mile of 1 inch core cable, and even as low as .000025 for traction rail bonds, several standard resistances are required.

It is usual to supply—

1 ohm standard to carry 1.0 amperes.

$\frac{1}{10}$ ohm standard to carry 10.0 amperes.

$\frac{1}{100}$ ohm standard to carry 50.0 amperes.

$\frac{1}{1000}$ ohm standard to carry 500.0 amperes.

These resistances are mounted behind a switchboard, on the front of which there is a multiple contact switch, potential terminals, and ammeter complete, as shown in Fig. 3, and are connected up so that either standard can easily be put in circuit. In some cases two extra brushes are fixed on the main switch arm, but insulated from it, and these touch on studs corresponding to the potential terminals of the resistances, so that when the main switch is turned to a particular standard, the potential circuit is made at the same time, thus avoiding and moving of the potential leads, rendering mistakes impossible, and increasing the speed at which tests can be made. Some manufacturers prefer to have these standards made of copper and then to neglect all temperature corrections, but it is better to have manganin or other alloy standards with a negligible temperature coefficient, and this for two reasons, first, because the standards are very difficult to obtain accurately, and secondly, because the cable is usually in a tank at some distance from the standards, and therefore difference of temperature has to be allowed for.

To make a test, connect up the instruments as in Fig. 2, select the standard whose value is nearest to that of the wire or cable to be measured, regulate the current by the ammeter in the standard circuit to the required amount, set the switch, V, so that it makes contact on the studs corresponding to the terminals, F, G, to which the potential wires, W W, from the standard resistance, R are connected, set the

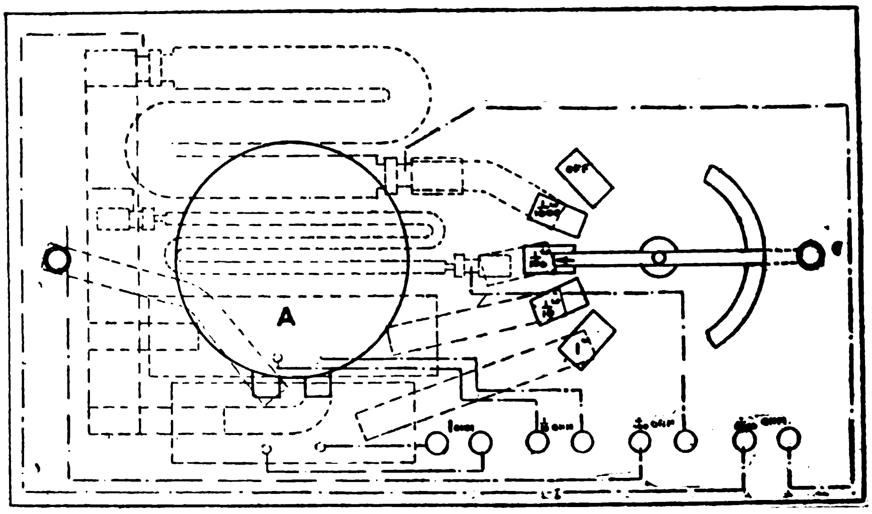

FIG. 3.

*From the "Electrical Review," London.

wheel, T, of the potentiometer so that a convenient figure, say 100, appears at the window, the key, W L, being at zero; obtain balance (no deflection of galvanometer when key is depressed) by varying the resistances, O, P, Q; now move the switch, V, on to contacts corresponding to W W, the potential wires from the cable R_x and move the wheel, T, and key, W L, until no current passes in the galvanometer; reading off the position of the wheel, T, at the window and of the key, W L, on the engraved scale, the resistances are proportional to these two positions of balance. Thus, supposing the 1 ohm standard to be in circuit and we balanced at 100 in the window and key at zero, and on turning the switch over to the unknown we obtained balance by setting the wheel to 40 and the key to 125 then the unknown resistance would be $\frac{40.125}{100} \times 1 = .40125$ ohm, that is, the instrument would read, direct if we read the figures straight from the wheel to the scale, thus .40125, the decimal place being seen at a glance.

Reference is made above to obtaining a balance by varying the resistance O, P, Q, until there is no deflection of the galvanometer; it is well to set these resistances approximately before putting down the galvanometer key, and thus avoid any banging over of the galvanometer coil and consequent disturbance of its zero.

These resistances may be calculated from the following formula:

$$\underset{\text{(Approx.)}}{O + P + Q} = \frac{E \times R \times l_1}{R \times I \times l} - R$$

Where E = E.M.F. of the battery on the potentiometer,

R = resistance of the standard in circuit,

I = current in R_s,

R = resistance of slide wire,

l_1 = position in scale divisions at which balance is wanted,

l = total length in scale division of slide wire.

The question often arises as to what current must be put through the standard resistances, so that accurate readings may be obtained without any fear of the cable being heated, and it is often stated that large currents have to be used in connection with potentiometer measurements. This is not the case, for rarely, except in the measurement of bond resistances, need a current exceeding 50 amperes to the square inch of copper be employed, and where, as is usual with cable makers, lengths of not less than one-eight of a mile are being measured, 10 amperes per square inch is ample.

For the measurement of the resistance of samples of copper wire a special board is provided, on which are mounted suitable current leading-in clamps for various sizes of wire, and knife edges at a definite distance apart, either 100 inches or 1 meter according to the standard with which the sample is to be compared, the knife edges acting as potential points; after the measurement of resistance a cutting knife is drawn over, and the wire nipped at exactly the 100 inches or 1 meter as required, this length being weighed in the usual manner.

The chief advantages gained in using the above instruments are:

The resistances of the potential wires between the cable standard and potentiometer do not come into the test, since when balance is obtained no current passes in the potential circuits; the cables can, therefore, be at some distance from the test house without any correction having to be made for connecting leads. The resistance is read direct in ohms, no calculation being necessary. Only four standard resistances are necessary to cover a very wide range of measurement; a six-dial Wheatstone bridge would have 68.

The potentiometer slide wire, except for a length of about 3 inches, is placed inside the containing box and therefore cannot be damaged, and as it is fixed on the under surface of the ebonite top, dust does not collect on the rubbing contacts.

The secret of successful potentiometer measurements is undoubtedly to keep the secondary cells in good working order.

THE ACCURATE MEASUREMENT OF ALTERNATING AND MULTIPHASE CURRENTS.*

BY G. L. ADDENBROOKE.

For many years past I have given much attention to this subject, and I have now the honor to lay the results of my experience and work before the International Congress. One main point which struck me several years ago was the desirability of looking at the question as a whole. In measuring alternating currents it is necessary to take into account the fact that if there is inductance or capacity in the circuit, as is usually the case, the current which flows is influenced by three factors: (1) The resistance of the circuit and the work done within it; (2) the inductance of the circuit; (3) the capacity of the circuit. The inductance and capacity effects being exactly opposite in phase, counterbalance each other as far as they can, the larger factor predominating, the phase of which will be either 90 deg. behind or in advance of the phase of the energy current, according as the self-induction or capacity of the circuit predominates. This current, when further combined with the energy current, produces a resultant current which is that actually flowing in the circuit, and which I prefer to call the "total" current rather than the "apparent" current and which, it is clear, will not be in phase with either of its components.

In carrying out the measurements in practice the wattmeter principle has come to be almost universally used in practice. Assuming that this principle is the one employed, there are three measurements which must be made to obtain the fundamental factors of an alternating current. When these factors are known other characteristics of the current can be deduced. A measurement must be made of: (1) The impressed volts; (2) the apparent amperes, or as I prefer to call them, the "total" amperes; (3) the effective amperes or watts. (If the effective watts are measured, knowing the impressed volts we can directly deduce the effective amperes.)

Having these quantities, we can directly deduce in addition the power factor, the angle of lag and the magnetizing or capacity current or their resultant, if both are present. Also, if we know the periodicity, the coefficient of self-induction of the circuit and other characteristics may also be obtained without further observations. Finally, if both inductance and capacity are present, by measuring this capacity we can with the above data find the inductance.

* Abstract of a paper read at the International Electricity Congress at Paris. From the "Electrician," London.

To adapt the electrometer for use as wattmeter I insert a series non-inductive resistance in the circuit to be measured, across which the quadrants are connected, while the needle is connected to the other side of the circuit so that the potential difference of the circuit is established between the needle and the quadrants. By arranging the instrument in this way and calibrating it properly, it is possible, under the right conditions, to make the electrometer a direct-reading wattmeter. Having the above-mentioned resistance necessarily in the circuit, it was clear that if it were possible to make an electrostatic voltmeter sufficiently sensitive to measure the drop of volts across this non-inductive resistance such an instrument so coupled would become a very handy form of ammeter. I have been able to attain such sensitiveness in the instrument employed as an ammeter that it is possible to get good readings with a drop of from 1 volt to 2 volts across the non-inductive resistance inserted in the circuit. As a matter of fact I am arranging my instruments in practice now so that the non-inductive resistance inserted in the circuit shall cause a fall of potential of about $1\frac{1}{2}$ volts as an average, which answers very well for the wattmeter also; this is a handy drop because it approximates to the E.M.F. of a Clark cell which is used for standardizing the instruments, and consequently the readings come near the portion of the scale for which the instruments have been standardized. To attain this object, namely, to always obtain a good deflection on the instrument, a set of non-inductive resistances formed of strips of manganin are used. These strips in practice are about a meter long, and a handy way to arrange them is by beginning with a wire or strip to carry, say, one ampere, to make the next strip carry about two amperes, and the third four amperes, so that about ten strips will usually cover the full range of currents which are likely to be required in practice. For special purposes, of course, higher or lower resistances can be made, and since the instruments take infinitesimal currents, the same set of instruments will measure currents varying from say, $\frac{1}{1000}$th of an ampere to 1,000 amperes or more, with equal percentage of accuracy in each direction if required; consequently the instruments are practically universal in this respect. By arranging these resistances so that they can be placed in parallel, the same deflection approximately on the instruments may, if desired, always be worked to.

As regards the measurement of currents of high voltages, there are two ways of proceeding. The instruments themselves can be made so that they can be directly connected to the high voltage circuit, but I usually prefer to employ instruments standardized for working direct on circuits of from 100 volts to 200 volts as a standard; and for higher voltages, to connect a high non-inductive resistance across the circuit, making the instrument connections across some known fraction of this over which there is a fall of 100 volts or 200 volts.

It now remains to describe this method and the design of the apparatus and instruments, and to show how they are used and applied to the purpose in view. Fig. 1 is a diagram showing the method of connecting the instruments in practice to a circuit on which measurements are to be made, and the figure also shows diagrammatically the method of standardizing the instruments and the switching arrangements by which the different connections are made; this is done by merely turn-

Digitized by Google

ing certain handles after the instruments are once set up.

In the diagram, A indicates the alternating current generating machine having a main circuit A_1, wherein is placed a non-inductive resistance *ab*, as mentioned above. From the point *a* a connection is shown to an omnibus bar or common terminal bar B to which most of the circuits hereinafter mentioned are joined. These are best arranged in the following order: C is a standard Clark cell, D is a battery of sufficient power to give rather more than the maximum voltage required for standardizing the instruments. I find a battery of small accumulators very convenient for this purpose, but if such a battery is not accessible the instruments can be standardized by making use of an electric lighting circuit instead, provided that readings are taken at similar pressures, which can be observed by connecting the electric light circuit to the voltmeter while readings on the wattmeter are being taken X is a variable resistance in series with the battery. E is a box of resistance coils so arranged that a resistance of 100,000 ohms is always maintained between the terminals, but by means of

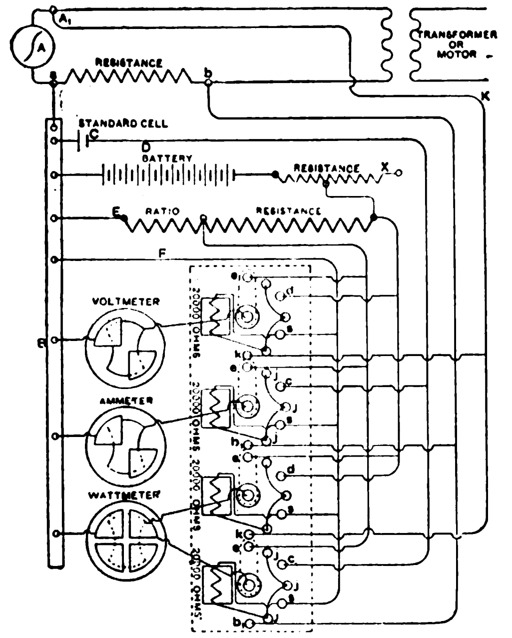

FIG. 1.

movable switches a third connection can be made to the resistance at any point desired. The outside terminals of this, which I call the "ratio" resistance, are connected to the common bar and to the resistance X, so that the ratio resistance forms a shunt across the battery and the resistance X. Let us suppose that the E.M.F. of the battery is 105 volts. By altering the resistance X suitably we can so arrange matters so that there is exactly 100 volts pressure between the outside terminals of the ratio resistance E, under which circumstances we can, by setting the switches of the ratio resistance to the proper points, obtain any voltage we like accurately between 0 and 100 volts. F is a short-circuit connection between the bar B and a terminal *s* in each of the switches indicated below whereby any of the instruments may be short circuited and their zeros adjusted. The electrostatic voltmeter, ammeter, and wattmeter are also connected to this bar. The voltmeter switch has our terminals, *e*, *d*, *s*, and *k*, the terminal *s* short-circuiting the instrument as above stated With the switch in contact with the terminal *d*, the instrument is connected to the battery D, and, similarly when in contact with the terminal *e*, the switch puts the instrument in connection with the ratio resistance E, so that a desired part or ratio of the whole resistance can be measured off and any required voltage within the limit of the battery put upon the needle of the voltmeter, its quadrant plates being connected to the bar B. By this means the voltmeter can be calibrated throughout the whole length of its scale. The termi-

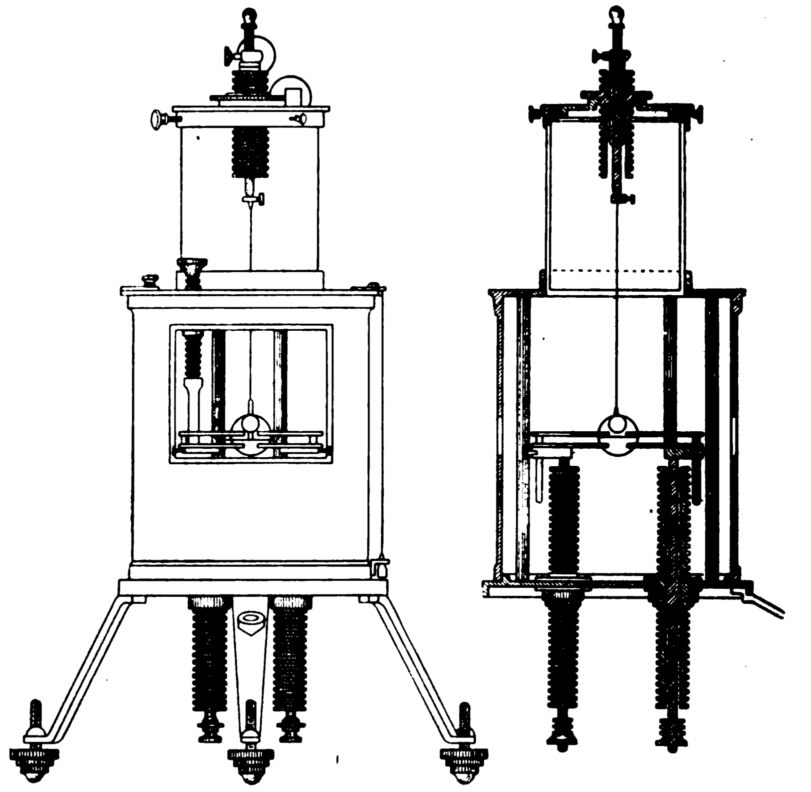

FIG. 2.

nal *k* serves to place the needle in connection with the circuit K, on which measurements are to be made.

The ammeter switch is provided with four similar terminals, indicated by the reference letters *e*, *c*, *s*, and b_1. The terminal is for connecting the needle with the standard cell C. The terminals *e* and *s* correspond to the similar terminals of the voltmeter switch, and the remaining terminal, b_1, connects the ammeter to the main circuit A_1, at the *b* end of the measured non-inductive resistance *ab*. The wattmeter has a double set of switch terminals, one set, *e*, *d*, *s*, k, being exactly the same and with the same circuit connections as for the voltmeter, and the other set, *e*, *c*, *s*, b_1, being similar to those of the ammeter switch.

In changing the instruments from one set of connections over to the other, it is very desirable to have a means of separately short circuiting each of the instruments through a high-resistance of about 20,000 ohms while the operation is performed, otherwise the quadrants must be left unconnected for a period of time, which sometimes leads to violent deflections of the needles when connected to alternating currents and from charges on the ebonite on other adjacent surfaces otherwise difficult to avoid. This is provided for by the intermediate contacts *jj*, in each of the switches, as shown in the figure, which are connected to bobbins containing a resistance of about 20,000 ohms, one for each set of switch contacts.

We now come to the instruments themselves. They are electrostatic, and are all built on the same general lines, which can best be seen by referring to Fig. 2, which represents the wattmeter. It may be noted that this one instrument will perform also the functions of a voltmeter and of an ammeter or low-reading voltmeter by simply altering the suspension of the needle and appropriately adjusting the quadrents. The instrument as shown is provided with very high insulation, so that it can be used for measuring high resistances, capacities, etc., but such insulation is not specially necessary where the instrument is to be used for measuring currents only, or as a low-pressure voltmeter.

The suspension consists usually of a flat phosphor bronze strip of the kind which was brought into use by Messrs. Ayrton and Perry, and which is so largely used in connection with the d'Arsonval galvanometer. This, of course, forms an excellent connection to the needle, so that there is no necessity to use sulphuric acid. Further, by using a specially light needle, I find that I can get sufficient decrement without any other form of damping, and consequently the needle may hang perfectly free in air, and there is nothing which can interfere with its proper movement in any way. It will be noticed that the quadrants are not made in the form of a box, as is usually the case, but consist of two sets of flat plates, the one set of which, usually the upper, is adjustable and can even be taken off altogether if required. This simple improvement, while it does not interfere with the action of the instrument in any way, greatly increases its range, adjustability and portability: in fact it is much like adding a universal shunt to a galvanometer. The needle, it will be noticed, can be moved up and down by means of a rack motion, and can thus be set in the center of the quadrants whatever the action of the upper and lower plates. For high voltages the upper plates can be removed altogether, and the needle removed some distance from the lower set of quadrants. On the other hand, the needle may be brought down close to the bottom set of quadrants and the top set brought down until the space between is not more than a millimeter. Under these conditions a deflec-

Digitized by Google

tion of 50 mm. to 100 mm., with the scale at a distance of 2 meters, can be obtained with the most sensitive strip with a pressure of 1 volt only when the instrument is connected up idiostatically, or as a simple voltmeter, and it is in this sensitive form that the instrument can be used as an ammeter by coupling it across a resistance in which from 1 volt to 2 volts is lost, as mentioned above. If we take this ammeter as our basis instrument, then the wattmeter to go with it must have a thicker suspension and be used with the quadrants further apart; in fact, it should be about $\frac{1}{10}$th of the sensitiveness of the ammeter. Then, again, the voltmeter requires to be much less sensitive still, this reduction in sensitiveness being obtained by the use of only one set of quadrants, and a much thicker and shorter strip, and in the latter case, owing to the strength of the torque, it is best to reduce the period by damping with oil. In each of the instruments, by taking off one or more of the top quadrants, and unscrewing the centering screws of the head, the head can be lifted off, carrying with it the needle, which can thus easily be changed. For carriage it is merely necessary to let down the needle on the bottom quadrants, and let down the top quadrants on the needle, which firmly clamp it, so that the instrument can be shaken or turned upside down without any damage resulting. Owing to the fact that the needles are flat and very light they are exceedingly little affected by vibration, so that the instruments can be used on upper floors and near moving machinery. In use it is well to put in the circuit of each needle a 250-volt lamp of 5 cp. I find this better than any form of fuse, as the current which can then pass through the instrument is too small to hurt the strip or needle, and at the same time instant warning is given by the lighting of the lamp if by any chance the needle should get attracted to the quadrants. The instruments are reflecting, and I usually arrange the scales at a distance of about 2 meters from the instruments.

With the help of the standardizing arrangements, approximate deflections are taken on them for the scale readings they are intended to give with given voltages on the needles and quadrants. The requisite sensitiveness is then obtained approximately by varying the distance between the upper and lower quadrants in two of the instruments, and the distance of the needle from the quadrants in the voltmeter till very nearly the deflections required are obtained. The scales themselves are on sliding supports, and the final adjustment is made by sliding the scales nearer to or further from the instruments until the given voltages produce deflections of the right length on the scales. In this way the instruments can be made to read watts, volts and amperes directly.

To standardize the wattmeter the needle switch is turned to the battery connection *d*, and the quadrant switch to the Clark cell connection *c*, the ratio resistance being set to 1,140 (supposing the resistance is 100,000 ohms as a total, and that the voltage across the ends of it is 100 volts). The quadrant switch is then turned so that the quadrants are connected to the positive end of this ratio instead of to the positive of the Clark cell, and the resistance X is adjusted so that whether the electrometer is connected to the Clark cell or to the point of ratio resistance the deflection is the same. It is obvious that under these circumstances the voltage across the outside terminals of the ratio resistance must be 100 volts. Consequently we know the voltage on the needle and the voltage on the quadrants which are the factors requisite for obtaining the constant of the electrometer. If the scale is graduated in millimeters it is now convenient to adjust the instrument and the distance of the scale, so that the reading is 144 millimeters. If this is done, then if the quadrants are connected across a resistance, the value of which is known in ohms or fractions of an ohm inserted in a circuit, and the needle is connected to the other side of the circuit, presuming the voltage does not fall very much below 100 volts, then the instrument will read directly in watts when multiplied by the reciprocal of the resistance, or if the resistances are numbered by their conductivities instead of by their resistances, then we have simply to multiply the reading by the conductivity, so that the instrument becomes a direct-reading wattmeter of almost universal range. Having now got 100 volts exactly across the battery by altering the value of the ratio in the resistance, the calibration of the electrometer throughout its whole scale can be made by simply turning the resistance switches to the appropriate points. If this is done it will be found that the scale is proportionate within half per cent. over a range of about 200 millimeters, and is within 1 per cent. over 300 millimeters. It will be observed that by calibrating under the exact conditions of use we do away with the necessity of applying any formula to the deflections of the instruments.

To calibrate the voltmeter, all we have obviously to do is to put it across the whole of the ratio resistance, since the drop across this is 100 volts exactly. The sensitiveness of the instrument should then be so adjusted by raising the needle or lowering it, and by moving the scale in or out that when the instrument is so connected it deflects to the point marked 100 volts on the scale. The instrument can be calibrated for any lower reading than this throughout the scale by altering the ratio point by the proper amount.

The sensitive electrostatic voltmeter which is used as an ammeter is now calibrated by connecting it directly by means of its proper switch across the poles of the Clark cell or the corresponding points on the ratio resistance, and this instrument also can further be calibrated in the same way throughout its whole scale by using the ratio. Owing to its delicacy and construction, however, the scale of this instrument is not quite so proportionate as in the case of the other two, and therefore it is well to construct a scale for it by setting the ratio resistance at the required points and noting the corresponding deflections. This can be quickly done, and when once the scale is made the instrument can afterwards be adjusted to read to this accurately, as described for the other instruments.

The instruments are now all calibrated, and nothing remains to be done but to turn their switches to the circuit connection, when they will give direct readings on any circuit to which they may be connected, the reading of the voltmeter being, of course, multiplied by the ratio of the high resistance across the circuit (if such is used), the reading of the ammeter being multiplied by the value of the known resistance (its conductivity) in the circuit and the wattmeter reading being multiplied by both these factors.

If the circuit is non-inductive the ammeter and voltmeter readings, when multiplied together, correspond with the wattmeter reading. If the circuit is inductive this, of course will not be the case, and if we divide the watts as shown by the wattmeter by the volts as shown by the voltmeter, then we get the effective amperes flowing in the circuit. On the other hand, the ammeter gives us the total, or as they are sometimes called, the "apparent" amperes flowing in the circuit. The ratio of these two gives us the power factor, from which, by merely consulting a table of sines or cosines, we find at once the angle of lag. If we know the periodicity of the circuit the coefficient of self-induction can be obtained without further observation.

By having a revolving contact connected to a small synchronous motor it is obvious that by the aid of the above instruments it is also easy to take a set of readings from which the actual curve of E.M.F. and current in the circuit can be plotted, with their lag or lead.

Where great accuracy is required in the readings it is obvious that all we have to do is to take a set of readings on any circuit and then turn over the switches one by one on to the ratio resistance, altering this until the deflections of the instruments on the circuit are reproduced. We then can read off directly and without calculation the continuous E.M.F.'s necessary to produce these deflections from which the value of the E.M.F. and the current in the circuit (the resistance across which measurements were made being known) is at once deduced.

It is obvious that the instruments are equally suitable for measuring continuous currents over almost any range, so that the instruments practically form a universal set of measuring instruments, whether for alternating or continuous currents. They can also be used for hysteresis and permeability tests, and for a number of other purposes to which I need not more directly allude.

For multiphase work, when the circuits may be unequally loaded, two sets of resistances may be used and the instruments can be quickly switched from one to the other. Or two sets of instruments may be used. Or instruments, particularly as wattmeters, may be employed with a double set of quadrants and double needle, the top needle being insulated from the lower; which receives its charge through a jar of acid. By means of the adjustable quadrants, it is easy to make both needles deflect equally for equal charges, so that when both are employed to read together their readings are added. For other purposes it is possible to use this double instrument as a zero instrument, and balance a known continuous against an alternating voltage.

The Sprague Electric Company's New Office.

The Sprague Electric Company has recently opened a branch office in the Security Building, St. Louis. Mr. C. B. White, who is well known in the Western electrical field, will have charge of the new office. He was formerly connected with the engineering department of the old Edison Electric Company, was located in Pittsburg, and performed considerable construction work in that territory. He was later electrical superintendent in charge of construction work with the Calumet Electric Street Railway Company, Chicago, and for the past two years has been connected with the Western Electric Company in the engineering and sales department. The Sprague Electric Company now has branch offices in Chicago, Boston and St. Louis, and agencies in all of the principal cities in this country and abroad.

SOCIETY NEWS.

American Institute of Electrical Engineers.

The 147th meeting will be held at 12 West 31st street, New York, Wednesday, October 24, at 8:15 P. M. The President will deliver his inaugural address on "The Paris Exposition of 1900." If time permits, some views of the exhibition will be shown by means of lantern slides. Mr. Frank W. Roller will also exhibit and explain the "Column Type of Indicating and Recording Volt and Ampere Meters."

Applications have been received from the following candidates for associate membership, which will be acted upon by the Council at its meeting, November 23, 1900: George Henry Sethman, Denver, Col.; Leon Byron Woodworth, Johannesburg, S. A. R.; George Alexander Walkhem, Vancouver, B. C.; C. M. Lowther, Ira R. Henry, New York; George Hafer, Jr., Cincinnati, O.; George Porter Baldwin, San Francisco, Cal.; Edward Andrew Deeds, Dayton, O.; Warren J. Ballou, Woonsocket, R. I.; Henry R. Leyden, Hamilton, Can,: Mikail de Chatelain, St. Petersburg, Russia; Frank, W. Springer, James Cezanne Kelsey, Minneapolis, Minn.; V. G. Converse, Pittsburg, Pa.

At the last meeting of the Executive Committee it was voted that hereafter the monthly meetings of the Institute be held on the fourth Friday of each month, instead of the fourth Wednesday as heretofore. This arrangement will go into effect in November, therefore the next meeting will be held on Friday, November 23, 1900.

The New York Electrical Society.

The 208th meeting of the Society will be held at the College of the City of New York, 23d street and Lexington Avenue, on Tuesday, October 30, at 8 P. M. The evening will be devoted to a symposium on the Paris Exposition and the Paris Electrical Congress. The subject will be profusely illustrated by lantern slides. Addresses on its various branches are expected from President Hering, of the American Institute of Electrical Engineers: Dr. A. E. Kennelly; Prof. F. B. Crocker; Mr. G. O. Mailloux; Mr. T. C. Martin and others who have visited the Exposition and participated in its Congress. Ladies' night.

Exports of Electrical Material from New York.

The following are the exports of electrical material and machinery, from the port of New York, for the week ended October 18:

Antwerp, 18 cases, $1,638; Argentine Republic, 519 packages, $15,953, 50 cases, $4,089; 13 cases electric meters, $1,000; 16 cases electric motors, $2,457; Australia, 5 cases, $809; Birkenhead, 16 packages motor trucks, $2,332; Brazil, 61 packages, $1,436; 8 cases, $7,814; Bristol, 7 packages, $426; British West Indies, 24 cases, $747; British East Indies, 13 cases, $1,460; Catania, 121 cases, $14,976. Central America, 40 cases, $732; China, 82 packages, $2,736; Cuba, 75 packages, $672; Dutch East Indies, 20 cases, $399; Ecuador, 68 packages, $2,497; 5 cases, $152; Florence, 1 case, $14; Genoa, 52 cases, $2,548; Glasgow, 72 packages, $18,325; 25 cases, $4,161; 40 packages, electric cable, $8,852; 15 packages trolley poles, $685; Hamburg, 68 packages, $5,526; Havre, 50 packages, $2,813; 1 case automobiles, $302; Japan, 64 cases, $14,227; Korea, 8 packages, $107; London, 239 packages, $14,669; 18 cases automobiles, $4,000, Liverpool, 63 packages, $14,691, 11 packages trolley material, $922; Mexico, 908 cases, $10,842, 50 packages automobiles, $16,991; Naples, 114 cases, $12,447; Newcastle, 231 packages, $41,400; Peru, 35 cases, $1,299; Porto Rico, 60 packages, $690; Riga, 19 cases, $3,918; Rostoff, 118 cases, $23,573; Southampton, 6 packages, $2,920; 7 cases, $880; Siam, 13 cases, $2,158; Trieste, 1 case, $140, U. S. Colombia, 131 cases, $1,830; Venezuela, 2 cases, $59.

PERSONAL MENTION.

Mr. Charles G. Wingate, formerly superintendent of the Huntington (N. Y.) Electric Railroad, has been appointed superintendent of the Ridgewood division of the Brooklyn Elevated Railroad system.

Mr. M. M. Dolphin of Kansas City, Mo., has been elected president of the Order of Railway Telegraphers.

Mr. Frank F. Healy has been engaged by the American Stoker Company of Erie, Pa., to go to Montreal, Can., and supervise the installation of eight large steam boilers and an engine of 1,500 horse-power for the Montreal Electric Lighting Company.

Mr. W. A. Coler has been reappointed superintendent of the Afton, N.Y., Central Telephone Station for another year.

INCORPORATIONS.

The Petersen & de Hosson Manufacturing Company, Chicago, Ill.—to manufacture electrical appliances. Capital stock, $25,000. Incorporators: H. Petersen, B. F. de Hosson and Morse Ives.

The Hannibal Railway & Electric Company, Hannibal, Mo. Capital stock, $100,000. Incorporators: E. Douglass Brewington, George D. Clayton, Edward P. Bowman and others.

The Economy Steam Heating & Electric Company, Sedalia, Mo. Capital stock, $50,000. Incorporators: Isaac H. Babcock, Charles R. Bishop, William D. Hall and others.

The Incandescent Mantel Company, St. Louis. Mo. Capital stock, $10,000.

The Mutual Traction & Illuminating Company, Somerville, N. J.—to manufacture electricity. Capital stock, $100,000. Incorporators: Jose Eugenio Marx, Max Marx and Alvah A. Clark.

The Electric Chemical Reduction Company, East St. Louis, Ill.—to reduce ores and other minerals. Capital stock, $3,500. Incorporators: J. W. Gannon, E. L. Anderson and J. E. Chambers, all of East St. Louis.

The Keystone Electric Light, Heat & Power Company, Maxatawney, Pa. Capital stock, $15,000.

ELECTRICAL PATENT RECORD.

[This department is edited by OSCAR A. MICHEL, Solicitor and Attorney for AMERICAN AND FOREIGN PATENTS, at 302 and 304 Broadway (Room 1204), New York City, also at 639 F street, N. W., Washington, D. C., who has been identified with this work before the U. S. Patent Office for more than fifteen years. Any inquiries upon the above subject as well as printed publications containing all information regarding the cost of United States and Foreign Patents, Trade Marks, Designs, etc., will be given free upon application by addressing OSCAR A. MICHEL, Nos. 302-304 Broadway, New York City, N. Y., or 639 F street, N.W., Washington, D. C. Copies of any patent published can be furnished upon payment of ten cents. When ordering give name, date and title of invention wanted.]

LETTERS PATENT ISSUED OCTOBER 16, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

659,694. High-Potential Trolley System. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Jan. 11, 1898.

659,823. Suspending Device for Trolley-Wires. William A. McCallum, Cincinnati, O. Filed Feb. 5, 1900.

659,982. Car-Fender. Joseph W. McKean, Charleroi, Pa. Filed Feb. 26, 1900.

660,065. Traction System. Frank J. Sprague, New York City, assignor to the Sprague Electric Company of New Jersey. Filed April 30, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

659,658. Electric-Arc Lamp. Richard Fleming, Lynn, Mass., assignor to the General Electric Company of New York. Filed April 4, 1898.

659,687. Electric Incandescent Lamp. Frederick Myers, New York City, assignor to Albert W. W. Miller, South Orange, N. J. Filed Sept. 26, 1899.

659,702. Means for Suspending Incandescent Electric Lights. Theodore Smith, Georgetown, Ill. Filed Feb. 26, 1900.

659,705. Clutch for Electric-Arc Lamps. Henry C. Spinney, Lynn, Mass., assignor to the General Electric Company of New York. Filed April 4, 1898.

659,706. Globe-Holder. Henry C. Spinney, Lynn, Mass., assignor to the General Electric Company of New York. Filed March 23, 1899.

659,710-659,711. Electric-Arc Lamp. George E. Stevens, Lynn, Mass., assignor to the General Electric Company of New York. Filed Nov. 14, 1898, May 31, 1889.

659,717. Contact Device. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed May 6, 1899.

660,047. Electric-Lighting System. Joseph I. Conklin, New York City. Filed March 28, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

659,660. Apparatus for Periodical Generation of Electric Currents by Motors of Irregular Driving Power. Max Gehre, Rath, Germany. Filed Dec. 19, 1899.

659,829. Dynamo-Electric Machine. Willard F. Richards Buffalo, N. Y., assignor to Charles M. Gould, New York City. Filed Jan. 2, 1900.

659,873. Snap-Switch Commutator. Charles G. Perkins, Hartford, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed June 28, 1900.

659,946. Electric Switch. George H. Whittingham, Baltimore, Md. Filed Feb. 5, 1900.

660,054. Controlling-Brake for Motors. Arthur C. Eastwood, Ensley, Ala., assignor to the Electric Controller & Supply Company, Cleveland, O. Filed May 14, 1900.

660,057. Astatic Armature for Electric-Supply Meters. Sydney Evershed, London, Eng., assignor to himself and the Evershed & Vignoles, Limited, same place. Filed July 21, 1900.

660,066. Method of Regulating Motors. Frank J. Sprague, New York City, assignor to the Sprague Electric Company of New Jersey. Original application filed April 30, 1898. Divided and this application filed June 23, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

659,691. Telephone-Transmitter. George B. Perkins, Medford, Mass. Filed Jan. 16, 1900.

659,759. Telephone-Exchange System. James L. McQuarrie, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Nov. 10, 1898.

659,768. Pilot-Signal for Telephone-Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 11, 1897.

659,789. Signal for Telephone Trunk-Lines. Henry M. Crane, New York City, assignor to the Western Electric Company, Chicago, Ill. Filed Jan. 10, 1900.

659,940. Telephone-Switch. Alfred Stromberg, Chicago, Ill. Filed June 13, 1900.

659,958. Telephone-System. William M. Davis, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, same place. Filed June 28, 1900.

659,959. Telephone-Exchange System. William M. Davis, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, same place. Filed June 28, 1900.

MISCELLANEOUS.

659,655. Apparatus for the Electrolytic Decomposition of Alkaline Salts, Edwin Edser, London, Eng. Filed March 31, 1899.

659,661. Coin-Controlled Mechanism for Phonographs, etc. George W. Gomber, Conyngham, Pa., assignor, by mesne assignments, to the American Multiplex Talking Machine Company of West Virginia. Filed March 18, 1899.

659,664. System of Electrical Distribution. Charles M. Green and John G. Callan, Lynn, Mass., assignors to the General Electric Company of New York. Filed June 30, 1900.

659,671. Magnetic Blow-Out or Fuse-Box. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 21, 1900.

659,697. Power-Transmitting Mechanism. Charles W. Richards and Winthrop M. Chapman, Needham, Mass. Filed Aug. 17, 1899.

659,716. Adjusting Reluctance of Magnetic Circuits. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed July 20, 1898.

659,725. Electric Time-Alarm, Simon Wolf, Essen, Germany. Filed Feb. 7, 1900.

659,729. Control Apparatus for Electric Carriages. Howard F. Eaton, Quincy, Mass. Filed March 25, 1899.

659,734-659,735-659,739. Phonograph. George W. Gomber, Conyngham, Pa., assignor, by mesne assignments, to the American Multiplex Talking Machine Company of West Virginia. Filed July 13, 1896, Aug. 18, 1896, April 8, 1897.

659,760. High-Frequency Transformer. Charles P. L. Noxon, Syracuse, N. Y. Filed Feb. 20, 1899.

659,766. Automatic Electric Cut Out. John H. Robertson, Morrison, Ill. Filed June 22, 1899.

659,793. Electric Alarm System and Testing Apparatus Leonard H. Des Isles, Cambridge, Mass., assignor to Roscoe F. Hersey, St. Paul, Minn. Filed Jan. 10, 1900.

659,824. Circuit-Controller for Electrical Mechanism. William A. McCallum, Cincinnati, O. Filed April 17, 1900.

659,828. System of Electrical Distribution. Edwin W. Rice, Jr., Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 16, 1899.

659,882. Spool for Electromagnets. George L. Weaver, Boston, Mass., assignor to Horace E. Harriman, Georgetown, Mass. Filed April 30, 1900.

659,891. Adjusting Device for Vacuum-Tubes. Thomas B. Kinraide, Boston, Mass. Filed Dec. 26, 1899.

660,021. Electricity Meter. William M. Mordey and Guy C. Fricker, London, Eng. Filed May 19, 1900.

660,043. Electrical Furnace. Wilhelm Borchers, Aachen, Germany. Filed Dec. 22, 1898.

660,045. Electrically-Actuated Sawmill Set-Works. William M. Carroll, Beaumont, Tex. Filed May 12, 1900.

THE TELEPHONE WORLD.

A Michigan Company Will Extend its Lines.

Manager Owen of the Allegan Telephone Company is making plans to extend his line from Allegan to Otsego and Plainwell. When the Michigan Telephone Company assumed the telephone property at Kalamazoo it also took charge of the exchange at Otsego and at Plainwell, and at once began to replace the independent 'phones by its own system as fast as possible, thus cutting off the connection which the Allegan Telephone Company formerly had at Otsego. Mr. Owen will remedy this by building a line of his own. He has also planned to build a line from Allegan to Gobleville and there connect with the Kibbie Telephone Company, which has several hundred 'phones in Van Buren County and taps every little town in that vicinity. The Allegan Company now has connection with the Citizens' Company of Grand Rapids, and the proposed line will connect all of the little towns in the vicinity with that city, and will give the Citizens' Company another line connecting with the Kibbie Company on the lake shore.

Last week Attorney John A. Delehanty secured from Justice Chase a writ of certiorari directed to the New York State board of tax commissioners, ordering them to review the assessments placed on the special franchise of the Hudson River Telephone Company in the Albany district. The writ was granted on the usual grounds that the assessment is unconstitutional and excessive, and on the further ground that it makes the company pay extra for its franchise. The company claims that it has laid free conduits and cables for the city of Albany, amounting in value to $3,000.

The Marathon County Telephone Company of Wisconsin has its line extended as far as Mosinee. It will touch Scofield, Marathon City, Rib Falls, Athens, Edgar, Fenwood, Stratford, McMillan and Marshfield. It will connect with the Citizens' line extending between Wausau and Marshfield. The new company has between 700 and 800 subscribers. The line will be completed by November 1.

The St. John's Valley Telephone Company has been organized at Van Buren, Me., with $2,000 capital for the purpose of operating a telephone line from the boundary line between Maine and New Brunswick, through Madawaska, Grand Isle, Van Buren, Hamlin Plantation, Grand Falls, N.B., Cyr Plantation, Connor Plantation, Caribou, and connect with any system at the terminal points. The officers are: President, Peter C. Keegan, of Van Buren; treasurer, T. J. Crocker, of Edmundston, N. B.

The parties to whom a franchise to put in an independent telephone system in Corsicana, Tex., was granted have secured a building for an exchange and announce that work on the line will begin shortly. The franchise was granted to F. B. McElroy and others, but it is understood the work will be inaugurated by Emory & Smith of San Antonio, Tex.

A new telephone company is to be organized in Elma, Wash., and it is expected that before long a line will be established giving direct communication between Centralia and Hoquiam, taking in Aberdeen, Montesano, Satsop, Elma, Porter, Oakville and Gate City, connecting with all the booms, lumber camps and saw and shingle mills. The promoter of the proposed line and company is O. H. Pearson of Elma.

President James E. Caldwell and Manager Leland Hume of the Cumberland Telephone Company, successors of the East Tennessee Company, recently inspected the Bristol, Tenn., exchange. They expressed themselves well pleased with the prospects in Bristol, and spoke of the probability of building branch lines from that place.

One of the recent important matters decided by the board of mayor and aldermen of Woodlawn, Ala., was the granting of a franchise to the Southern Bell Telephone & Telegraph Company.

The Eugene, Ore., telephone exchange will have a new switchboard next month. A new line is being extended to Jasper, Thurston and Waterville, Ore., and may be carried on to the Blue River mines.

The Delaware and Atlantic Telegraph & Telephone Company has lately been improving its lines in Wilmington, Del. An extension is being made to Edgemoor, where several instruments will be installed.

The Northwestern Telephone Exchange Company reports a net gain of 519 subscribers in September, making a total number of 20,686 subscribers on September 30.

The telephone exchange in Le Roy, N. Y., is constantly growing.

Duplex Telephony.

Mr. E. A. Martin, Inspector of the Central Union Telephone Company at Davenport, Ia., has been experimenting for about a month upon the problem of duplex telephony, the successful solution of which means a million dollars to the inventor, according to a standing offer made by a large electric concern of Chicago. It has been generally conceded to be within the range of legitimate endeavor being akin to duplex telegraphy, but has so far baffled those who have given it any thought, and it was to stimulate interest in a feature of high scientific value, that a large reward was offered. Mr. Martin claims to have found a solution to the problem. He does not, however, propose to give a description of his mode of operation until after a caveat for a patent has been filed.

The addition of nearly a thousand miles of new territory and the bringing of New Orleans, La., into direct telephone communication with between 300 and 400 towns in East Kentucky and Tennessee, will shortly be an accomplished fact. This important extension of long distance telephone service out of New Orleans is the outcome of the recent purchase by the Cumberland Telephone and Telegraph Company of the line of the East Tennessee Telephone Company. The latter company operated over 900 miles of wires in sections of Eastern Kentucky and Tennessee not traversed by the Cumberland Company. The company had nearly 400 offices established in these two States, including two large exchanges at Chattanooga and Knoxville, Tenn., and one at Paducah, Ky. As a result of the purchase all these offices will be connected up with the Cumberland Company's lines, thereby greatly extending the long distance service and giving to the latter company a much larger field for operations, particularly in the two States mentioned.

Plans have been started in Charleston, S. C., by the Gordon Telephone Company to give long-distance connections out of that city. The plan by which this will be done has not been announced, as it is said the Gordon people are not prepared to let the public into their confidence just at this time, although arrangements are well under way. Messrs. Cecil G. Fennell and Reginald F. Fennell, secretary and general manager of the company, will begin at once to complete their arrangements by which the long distance service can be established. While this work is being done the company will increase the capacity of its local system, and make additions and improvements to meet the extra amount of business which will come about when the out of town lines have been opened.

The Spring Telephone Company, whose lines extend through the western part of Snyder County, Pa., has sold its lines, instruments and effects to the Penn Telephone Company for $12,800. This purchase is the beginning of a large deal. The next move will be the consolidation of the Penn, Tuscarora, Home, Shamokin Valley, Schuylkill and Montour and Columbia Telephone Companies.

The city of Glasgow, Scotland, has a population of 600,000. It is asserted that telephone service in a large city costs the operating company more than in the smaller cities. Glasgow, it is claimed, has a thoroughly efficient system that costs subscribers $25.25 a year.

The Sparta, Mich., Telephone Company was lately reorganized. Charles H. Loomis is president. Dr. D. J. Wallace, J. Hisey and August Johnson form the executive committee. Bruce N. Keister is secretary and treasurer. The company will get a one hundred drop switchboard and affiliate with the Citizens' Telephone Company of Grand Rapids.

It is said on good authority that A. R. Warner of Cleveland, O., acting for the United States Telephone Company of Cleveland, has purchased the franchise of the Citizens' Telephone Company of Mansfield, O. The Citizens' Company has never done anything further than to take subscriptions for telephone service.

Chicago so far, it is claimed, is the only place where a school has been established for the systematic teaching of the telephone operator, who can receive there a training in all that would make her the expert that practice finally does.

The Erie Telegraph & Telephone Company, which will run lines between Troy N. Y., and Cleveland, O., has filed an amended certificate of incorporation with the Secretary of State. The capital of the company is $15,000,000.

The St. Croix Telephone Company has placed a new wire on its line in Osceola, Wis., for the exclusive use of business men.

The Northern Illinois Telephone Company of Sandwich, Ill., has increased its capital stock from $30,000 to $250,000.

An informal meeting of the board of aldermen of Gardiner, Me., was held a short time ago, and they were practically unanimous in favor of admitting the Eastern Telephone Company. About a year ago the Eastern Telephone Company petitioned for the right to place its poles in that city and was rigorously opposed by the new England Telephone & Telegraph Company, the aldermen at the time being a tie. Since then the sentiment of the community has been found to be practically unanimous in favor of the admission of the company.

A move was made recently at Cincinnati, O., at the meeting of the Board of Legislation, when Mr. Mullen introduced an ordinance to grant to the Kleine Electrical Engineering Company a franchise to engage in the telephone, telegraph, fire-alarm, burglar-alarm and messenger business in that city for twenty-five years. Mr. Mullen would vouchsafe no information regarding this move further than that he meant business, and that the ordinance would speak for itself.

Manager Atwood of the local system of the Northwestern Telephone Company of Jamestown, N. D., will shortly establish long distance stations at Rogers, Hannaford, Dazey and Cooperstown, N. D. The wires have been strung from Sanborn to Cooperstown, and all that is now necessary is to complete the connections. The line will not be extended beyond Cooperstown this season.

The Sunset Telephone Company, which recently began construction of a building for local headquarters at Tacoma, Wash., has suspended work until authority can be secured from the city to bury its wires. A new ordinance is being framed which will give the company power to lay wires in conduits.

C. H. Fisher, manager of the telephone exchange at Granbury, Tex., writes us that there is need of a telephone expert in that vicinity as many telephones and switchboards are out of order. He adds that a good price would willingly be paid for the services of a good man.

The Nichols Law State Tax Board has completed valuation of the City and Suburban Telephone & Telegraph Association of Cincinnati, O., appraising it on a basis of its capital stock and earnings at $743,179, an increase of $7,141 over last year.

The Rawson Electric Company of Elyria, O., known as the Home Telephone Company, which was granted a franchise by the Lockport, N. Y., common council last spring, began work a short time ago on the construction of a new telephone exchange.

The telephone line between Monroe and Dusty, Ore., is now completed. The force employed in its construction has gone to Brownsville, where another line is to be put up, connecting that town with Sweet Home, Ore.

The Peoria & Eastern Automatic Telephone Company of Chatsworth, Ill., recently changed its name to the Peoria & Eastern Telephone Company. The capital stock was increased from $12,000 to $25,000.

Guy M. Gest has been awarded the contract for building the subways for the complete telephone conduit system at Racine, Wis. The system will be about six miles long.

TELEPHONE INCORPORATIONS.

The West Canada Telephone Company, Vernon, N. Y.—to operate telephone lines between villages in Herkimer and Hamilton Counties. Capital stock, $3,000. Directors: J. W. Jenkins and J. E. Jenkins, of Vernon, and S. E. Harvey, of Grant.

The Roachdale Union Telephone Company, Roachdale, Ind. Capital stock, $100,000. Incorporators: Benjamin B. Cline, Charles A. Edwards, Isaac E. Weddel, Joseph Cline, W. Turpie, Robert Britton, M. L. Pope, A. G. Cook, E. O. Coffman and A. C. Lockridge.

The Andover Electric Telephone Company, Andover, O. Capital stock, $6,000. Incorporators: C. E. Harmon, S. R. Wood, W. Grubham, V. M. Cole and W. Webb.

The Paris and Minter Telephone Company, Pattonville, Tex.—to operate a telephone line from Pattonville to Paris, Minter and other points in the counties of Lamar, Delta and Red River. Capital stock, $2,500.

The Central Energy Telephone Company, Frankfort, Ind. Capital stock, $30,000. Directors: John H. Murphy, Murat W. Hopkins and William Pogue, all of Indianapolis.

The Johnson County Mutual Telephone Company, Sharon Center, Ia.—to do a general telephone business. Capital stock, $1,000. Incorporators: G. W. Wagner, J. P. Memler, L. G. Shaver and T. N. Wagner, all of Sharon Center.

GENERAL NEWS.

What is Going On in the Electrical World.

LIGHTING.

Arkansas City, Ark.—F. D. Hagar and J. F. Small of St. Louis, Mo., are organizing a stock company to build waterworks, an electric light plant, etc.

Avon, N. Y.—The electric light company of this place has agreed to furnish light for the streets upon the rate of the old contract until June next, after which time there is to be an extra charge of $2 per lamp.

Beaver Falls, Pa.—At a meeting of the citizens of College Hill it was decided to have the people vote upon the question of building their own electric light plant. An estimate of $13,000 was reported and the decision arrived at was unanimous.

Bloomington, Ill.—The Chicago & Alton Railroad will erect a power house and an electric light plant; engines, boilers, dynamos, etc., will be required.

Chicago, Ill.—The city council has declared for the municipal ownership of all gas and electric light plants. A law to that effect will be drafted for submission to the next General Assembly.

Corsicana, Tex.—Mayor S. W. Johnson in his message to the council recommends the building of an electric light plant by the city.

Des Moines, Ia.—R. H. MacMullan, manager of the Edison Light Company, recently said that the company will shortly begin the work of putting its wires under ground.

Florence, Ala.—E. J. O'Beirne has been granted a franchise by the council to build an electric light plant here. Arrangements have also been perfected to light Sheffield and Tuscumbia from the same plant. The power plant will be built on the Tennessee River.

Grundy Centre, Ia.—The electric light plant here was recently destroyed by fire.

Hutchinson, Minn.—W. E. Harrington, E. Drew, H. H. Ames and others have formed a company with a capital of $25,000 and will at once receive plans and specifications for an electric light plant.

La Crosse, Wis.—This city is discussing the question of erecting a municipal electric lighting plant.

Lexington, Ky.—The Lexington Railway Company will make improvements to its power house, including the installation of an incandescent engine with a capacity of 3,000 lights. Mr. Hathaway, general manager, can be addressed.

Little Falls, Minn.—The Little Falls Electric Light Company will purchase a new incandescent light machine to replace the one damaged recently.

Marblehead, Mass.—The city council intends to enlarge the present electric light plant at a cost of about $10,000.

Millen, Ga.—The town council lately granted to the Millen Cotton Mills a franchise to use the streets for electric light poles.

Montesano, Wash.—A franchise has been granted to Chester H. Kiehl and others for an electric light and power plant, the franchise lasting for fifty years. The work must begin within six months.

Mora, Minn.—The plant of the Mora Milling & Electric Light Company burned a short time ago. Loss, $12,000; insurance, $7,000.

Mt. Gilead, O.—The voters of this city have decided in favor of an electric light plant. J. C. Fish of Shelby was granted a franchise.

Mt. Morris, Ill.—E. F. Thomas has secured a franchise for installing an electric light plant here.

Mt. Vernon, Ill.—This place has floated 4 per cent. bonds for $98,500 to be used to purchase water and electric light plants.

Neoga, Ill.—The contract has been awarded by the city council for the erection of an electric light plant.

New Springfield, O.—H. O. Brown is contemplating the erection of an electric light plant to furnish light for his store and other business places and residences in this town.

North New Portland, Me.—C. H. Bartlett will shortly erect an electric light plant at this place.

Orlando, Fla.—The city council has advertised for a proposition to light the city by electricity.

Pekin, Ill.—The citizens of this place are discussing the question of erecting a municipal electric light plant.

Penn's Grove, N. J.—An electric light plant will soon be built here.

Rosebud, Tex.—W. H. Freeman of this place is authority for the statement that the Southern Electric Light Company will erect an electric light plant to operate about 25 1,000 cp. arc and 2,000 16 cp. incandescent lights.

Springfield, Ill.—A new light plant costing $20,000 will be put in the State Capitol Building.

Tampa, Fla.—At a council meeting held a short time ago W. H. Frecker moved that the city attorney be instructed to prepare an ordinance to provide for a bonding election on the water and electric light questions. The motion was unanimously adopted.

Tennille, Ga.—A franchise for furnishing this place with electric lights has been given the cotton factory people, and they will put in a plant at once. The plant will be of sufficient power to furnish Sandersville, a city some three miles distant, with lights also.

Tionesta, Pa.—D. W. Clark, village secretary, is preparing estimates for an electric light plant to be erected here.

Tiptonville, Tenn.—F. W. Luscombe is the promoter of the electric light plant now being agitated in this place.

Towner, N. D.—F. M. Dompier will in the near future install an electric light plant in his new block just completed in this city.

Weiser, Idaho.—The city clerk was lately instructed to advertise the sale of $45,000 bonds for the purpose of building an electric light plant.

Woodstock, Ont.—The ratepayers of this place will vote on a $30,000 by-law for electric light, $14,000 to purchase the electric company's plant and $16,000 to renew and extend it.

York, Pa.—The Merchants' Electric Light, Heat & Power Company has been formed with $750,000 capital stock and an electric plant will soon be built. Charles H. Bear is at the head of the movement.

STREET RAILWAYS.

Chicago, Ill.—The trolley car and the overhead wire have replaced the storage battery cars of the Chicago Electric Traction Company between Morgan Park and 79th and Halsted streets.

Galion, O.—The Ohio Central Traction Company has decided to construct the Crestline branch of the electric road and work on the same will be begun early in the spring. It is estimated that the Crestline extension will cost about $75,000. F. C. Boyd is vice-president of the company.

Goshen, Ind.—A company of 35 local capitalists will soon be formed to construct an electric line from this city to Lake Wawasee. The road is to be built by J. J. Burns.

Indianapolis, Ind.—The Indiana & Ohio Traction Company was lately incorporated with $750,000 capital stock to build an electric road to connect the cities of Marion, Huntington and Ft. Wayne in Indiana and Hicksville in Ohio. J. H. Simonson, P. R. Smith, J. D. Olds and J. W. White are interested.

Marinetta, Wis.—According to a statement made by I. Stephenson, president of the Escanaba & Lake Superior Railway Company, the road will be operated by electric power within two years.

Mt. Pleasant, O.—J. A. White of this city is interested in an electric line extending from Newcomerstown to Wheeling via Uhrichsville and Cadiz. Mr. White is now seeking to interest capitalists for its early construction.

Pine Bluff, Tenn.—G. F. Crater and R. M. Unall, capitalists from New York, have been here with a view to building an electric street railway and light plant.

Portland, Ind.—The Oil Belt Traction Company, a corporation organized about one year ago to build an electric road from here to Huntington, reports that funds have been secured and work will begin within 60 days. The road will be 61 miles in length.

Saginaw, Mich.—It is now practically settled that the Saginaw suburban electric railway will be in operation by July 1, 1901.

Upper Sandusky, O.—The Galion-Bucyrus electric line will be extended from the latter place here, and $125,000 have been appropriated for the same. The distance is 17 miles.

Waterbury, Conn.—The New Haven road will equip its New England line between this city and Bristol with electricity.

MANUFACTURING.

Denver, Col.—The Gardner Electric Drill & Machinery Company, a new Denver corporation having a capital stock of $1,000,000, is arranging for the purchase of a site upon which to build a factory for the manufacture of tools and machinery.

Pasadena, Cal.—The arrangements for pushing the work of the California Electrical Manufacturing Company are progressing. In its earlier operations the company will be principally engaged in the manufacture of glass for use in connection with electrical appliances, but it will ultimately undertake the manufacture of sockets and switches and all the brass and bronze standard goods used in electrical work.

COMPANY MATTERS.

Albany, N. Y.—The New York & Queens Electric Light & Power Company filed with the Secretary of State October 17 a certificate of increase in the number of its directors from three to seven, and of the election of Harrison E. Gawtry, G. F. Baker and J. Levering Jones as additional directors.

Boston, Mass.—It is reported that the Boston & Montana Company is figuring on enlarging the electrolytic plant so as to give it a capacity of 8,000,000 or 10,000,000 pounds of copper each month.

Des Moines, Ia.—The Tri-City Electric Company of this city has been awarded the contract for wiring the new collegiate building at the State University and for furnishing the electrical fixtures.

Gates' Mills, O.—A recent fire destroyed the car sheds of the Cleveland & Eastern Electric Railway Company here.

POWER AND TRANSMISSION PLANTS.

Hanford, Cal.—An electric company has been formed here with a capital stock of $5,000,000, with A. Guthrie president and E. Kanutzs secretary. The object of the concern is the erection of a plant to develop electric power on the San Joaquin River, 180 miles from San Francisco.

Millbury, Mass.—The Worcester & Blackstone Valley Street Railway Company has leased the Millbury Cotton Mill for a power plant. The capacity is 250 horse power.

Newark, N. J.—The Hunterdon Water Power Company has been formed here to distribute water and electric power with a capital stock of $2,000. Among those interested are E. A. Day, Morristown; W. T. Day, Elizabeth, and J. T. Congleton, Newark.

Riverside, Cal.—There is a report current to the effect that the Chase Nursery Company is about to install an 800 horse power electric plant at Ethanac, which will be used later in connection with a sugar beet project.

MINES.

Dawson City, Can.—It is claimed that the electric light companies of this city are making preparations to furnish power from Dawson to many of the mines on Bonanza and Eldorado creeks. The main electric plant of Dawson has been increased to 800 horse power and a 500 horse-power boiler is being installed.

AUTOMOBILES.

Des Moines, Ia.—Jesse O. Wells and L. J. Wells of this city are thinking of starting an automobile factory. The machines which have been turned out have given satisfaction, but the promoters want to perfect the details of manufacture.

Farmington, Conn.—A plan is on foot to establish an electric charging plant here for the use of those visiting the Elm Tree Inn and the Country Club in automobiles.

Homestead, Pa.—Dr. J. Boyle, F. W. Brockman and H. C. Keyes are the promoters of the company formed here for the purpose of manufacturing automobiles.

Williamsport, Pa.—The Union Automobile & Transportation Company has been formed here for the purpose of transporting persons in automobiles. The capital stock of the company is $500,000.

Wilkes-Barre, Pa.—Arthur F. Huey, general superintendent of the Ricker Motor Vehicle Company of Elizabethport, N. J., and Mr. Gunster, the president of the local company here, have lately been looking at properties with the view of obtaining a suitable stable for the 'buses. They not only have to be sheltered, but there must be electrical appliances for charging the batteries.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16[illegible]@16[illegible]c.; **Lake**, 16[illegible]@16[illegible]c.; casting, 16[illegible]@16[illegible]c.

The Bell Telephone Company of Philadelphia has declared the regular quarterly dividend of 2 per cent., payable October 30.

The Columbus Railway Company has declared a dividend of 1¼ per cent. on its preferred stock, payable November 1 to stock of record October 18.

The Chicago Edison Company has declared a quarterly dividend of $2 per share, payable November 1. Books closed October 23 and reopen November 1.

The Trinity Copper Company has been incorporated at Trenton N. J., with a capital of $6,000,000. The company proposes to engage in all kinds of mining, but particularly copper.

The National Carbon Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable November 15. Books close November 5 and reopen November 16.

The regular quarterly dividend of 1½ per cent., guaranteed by the Union Traction Company of Chicago on the West Chicago Street Railway Company's stock, is payable November 15. Books close November 5.

The Rapid Transit Commission will ask permission of the city Government to begin the underground road to Brooklyn at an estimated cost of $8,000,000 but for legal reasons the work cannot be begun before next fall.

The Birmingham (Ala.) Railway, Light & Power Company, capital $1,500,000, has been formed by the consolidation of all the local traction companies. In all $3,500,000 bonds will be issued, of which $1,500,000 are for extensions and improvements.

Figures of production export of copper for September are as follows: Produced by United States reporting mines, 17,986 tons; by outside (estimated), 3,400 tons; by foreign reporting mines, 7,145 tons. Export: 10,245 tons, all in tons of 2,240 pounds of fine copper.

Assistant Corporation Counsel Carr of Brooklyn has brought a new suit against constituent lines of the Brooklyn Rapid Transit Company for about $300,000, claimed to be due as assessments for street paving and percentages of net earnings which were promised to the city.

A trust mortgage was filed at Saginaw, Mich., recently by the Saginaw Suburban Railway to the New York Security & Trust Company, in the sum of $800,000, to secure an issue of bonds for that amount. The bonds are to have a sinking fund of 10 per cent. of the annual net earnings of the company.

It is figured in street railway circles in New York, that under the readjustment of street railway taxes in Manhattan Island alone the assessment upon which the Metropolitan Street Railway Company must pay taxes, is raised from $5,000,000 to $35,000,000 while the assessment of the Manhattan Elevated Railway Company is increased only from $28,000,000 to $30,000,000.

The recent strength in United States Rubber common stock is attributed to the belief in certain quarters that dividends on it will be resumed before very long. One of the directors says that the question will not come up for consideration before the board of directors until early in January. At that time the company will be in a position to approximate at least the results of the current fiscal year, which closes in April.

The normal yearly increase in gross earnings of the Boston Elevated or West End Street Railway is about 5 per cent. If official estimates that the gross earnings for the year ended September 30, 1900, will show an increase of $500,000, are fulfilled, the percentage will be 5.2. In 1899 the increase was 5.5 per cent. In the last eleven years, however, gross receipts have increased 100 per cent., as in 1889 they were $5,249,9[illegible]2, and in 1900 they will be about $10,200,000.

The Boston and Worcester syndicate, which last March secured control of six electric roads operated in and around Worcester, Mass., is now before the railroad commissioners seeking to effect a consolidation of four of its properties for the purpose of more economical operation. Reports that these companies are to be consolidated with the Massachusetts Electric Companies are erroneous. They are not located within 15 miles of a connection with the Massachusetts Companies lines. The syndicate has in the vicinity of $2,000,000 invested in Worcester street railway properties, but as yet no corporation has been formed to take them over.

It is not probable, says the Boston "News Bureau", that the Western Union Telegraph Company will make as good a showing the last quarter of this year as for the corresponding period a year ago, notwithstanding the increased business that may arise from the election, as the Postal Telegraph Company has succeeded in capturing the German cable business which formerly went by the Western Union. This business amounted to over 300,000 messages a year, and while for years one could send a cable by the Postal lines to Germany, the return message under the Government system always went by the Western Union. Now the situation is reversed and the return messages are all by the Postal Telegraph Company which has the direct German connection.

No doubt exists in the minds of conservative people in the Street says the Philadelphia "Stockholder" that the Brooklyn Rapid Transit Company will before many months have elapsed be under control of Metropolitan Street Railway interests. Nothing official on this head can be learned, but strong intimations come that a deal looking to that end is impending. A gentleman in position to secure exclusive knowledge concerning both companies stated recently that Brooklyn Rapid Transit stock is "about the best buy on the New York list." He added that the stock will shortly start on its road to 65. What makes stories of Metropolitan control appear all the more feasible is the geographical position of the two systems. Both could be linked without necessitating the outlay of any large sum of money and the result of this cannot be anything but apparent.

EDITORIAL NOTES.

An Important Patent Suit.

In the issue of ELECTRICITY of June 27, 1900, we referred to the infringement suit of the Electric Smelting and Aluminum Company of Cleveland against the Carborundum Company of Niagara Falls, which had been dragging through the courts for several years. Now our Washington correspondent informs us that a petition for a writ of certiorari brought by the Carborundum Company against the Electric Smelting and Aluminum Company before the United States Supreme Court has been denied.

The appeal was brought from the United States Circuit Court of Appeals for the Third Circuit, to which Court it was brought from the United States Circuit Court for the Western District of Pennsylvania, in which Court the Electric Smelting and Aluminum Company brought a bill of complaint against the Carborundum Company for infringement of certain Letters Patent No. 319,795, granted to E. H. and A. H. Cowles, June 9, 1885, for a process of smelting ores by the electric current, known as the Cowles Process Patent; and Patent No. 319,945, granted to the same parties on the same date, for an electric smelting furnace, known as the Cowles Apparatus Patent. In the original bill a third patent was brought in question, but the case was later restricted to the two already named.

The case was heard before the Circuit Court, and on July 26, 1897, a decree was found for the defendant as follows:

1. That the defendant did not infringe the Cowles Apparatus Patent.

2. That the method of making carborundum used by the defendant differed from the method of the Cowles process, both in respect as to process, preparation of ingredients, means and objects, and did not infringe.

The case was argued before the Circuit Court of Appeals in 1898, and on January 30, 1899, that Court ordered a reargument, which was had on September 19-20, 1899. The Court filed its opinion on May 28, 1900, to the effect that the defendant had infringed certain claims of the Cowles Process Patent, and had not infringed the Cowles Apparatus Patent; it reversed the decree of the Circuit Court, with directions to enter a decree for the complainants, but without costs incurred theretofore by either party.

The Cowles process requires, first, that the operation is to be metallurgical. It begins with an ore, metalliferous in character, broken or granular in condition, which being smelted or reduced in a described manner, produces a metal or an alloy of metals. It requires a material or substance capable of carrying an electric current of high potential, yet not doing so readily, but only with difficulty; and hence such material must furnish considerable electrical resistance to the passage of the current. The material commonly used for the purpose is carbon in granular condition; these two ingredients, the ore and the carbon, are then mixed together into a mass, and when mixed are charged into a suitable retort or close chamber, and a powerful electric current is passed through it. The grains of carbon which have been distributed through the mass take and carry the current. They become highly heated by the resistance which they give to the passage of the current through them. Being in contact with the grains of ore, also distributed through the mass by the mixing, they heat up the grains of ore to the same high temperature, and the ore is thus smelted or reduced. In other words, the grain of carbon in the mass being heated by electrical resistance while in contact with the grains of ore in the same mass, communicate their heat directly to the latter, with reference to effecting the desired smelting or other reduction of the ore.

This mixing of the carbon and the ore into a single mass, whereby to secure contact of carbon and ore, grain by grain, is specifically described in the patent both as to how it is done, and as to why it is done, and, also, as to the results expected to be obtained by the process, as follows:

(a) As to the how and why it is done:

"The ore or like material to be reduced . . . is usually mixed with the body of granular resistance material (carbon), and is thus brought directly in contact with the heat at the points of generation; at the same time the heat is distributed through the mass of granular material, being generated by the resistance of all the granules, and is not localized at one point or along a single line."

(b) As to the results:

"The electrical energy is more evenly distributed, and the current cannot so readily form a path of highest temperature and consequently of least resistance through the mass, along which the entire current or bulk of the current can pass."

No other procedure, other than that de-

Digitized by Google

scribed above, is claimed for the Cowles patent, and it is necessarily limited in character.

As to the method pursued by the Carborundum Company. Some five or six years after the date of the Cowles patent, Mr. E. G. Acheson, now the president of the company, in the course of some experiments which he was making, discovered a new substance, that is to say a substance which was wholly unknown in the practical arts and equally unknown in the scientific world; it consisted of a compound of silicon and carbon and subsequent investigation showed it to be not only new but of enormous practical value in the mechanical arts, and as a convenient trade name he called it carborundum.

While it is used in a crude form, that is in the form in which it is manufactured, for a few purposes, as in steel making, its chief value is as an abrasive or grinding material. It has almost entirely supplanted the use of emery in the mechanical arts, as for similar purposes it has been found to be from three to eight times more efficient than emery in different classes of work.

The process is as follows: A mixture is prepared of fine granular carbon and sand, with a percentage of salt and sawdust, called the "charge-mixture." In the furnace used by the Carborundum Company this mixture is surrounding a central core, made of coarse granular carbon. No ore or other material enters into its composition. It is of about the diameter of a flour barrel, and about 16 feet in length. The electric terminals of the circuit are electrically connected with the ends of the core at the opposite ends of the furnace. The charge-mixture surrounds the core throughout its length, on top, bottom and sides, to a thickness of about two feet. In this process the electric current follows or traverses the core alone, and does not follow the charge mixture. On this point the Circuit Court said:

"While, as we have said, absolute certainty is impossible, we are, by a most patient and detailed study of the case, left to two conclusions. First, the weight of the proof and the reasons advanced, failed to show that a substantial, effective part of the current passes through the charge-mixture in respondent's process, and secondly, the clear weight of the evidence tends strongly to show that the working effective current is confined to the central core in respondent's workings."

It is claimed by the Carborundum Company that the two processes are directly the reverse, the one of the other.

The reasons for which the case was brought to the Supreme Court were:

The magnitude of the public interests involved in a correct determination of this cause. It being claimed that if the conclusions arrived at by the Court of Appeals be correct, that the Cowles Process Patent can lawfully dominate the use of a distributed and a non-distributed current, then it is believed that a onsiderable percentage of the manufacturing establishments now centered around the electric-generating plant of the Niagara Falls Power Company will become subject to the patent in question: specific reference being made to that Company, not because it was the only company of its kind, nor because its interests were exceptional or exceptionally great, but because of its organization, its purpose, and the character and extent of its business being matters of general public knowledge, and was thus best suited for the purposes of illustration.

The Niagara Falls Power Company has an investment represented by $13,000,000 securities, and it has a large interest in the correct solution of the problem. The Carborundum Company is only one of the many manufacturing plants that buys its electric power from the Niagara Falls Power Company: the amount of capital which it has invested in the business of making and selling carborundum and carborundum products is something over $400,000; its entire plant and apparatus is exclusively for this purpose. Its production is about 1,700,000 pounds of carborundum per year. This carborundum is used largely in steel making, in granite polishing, for which it supplies over 90 per cent. of the abrasive material used in this country and in Scotland: in the dental profession; in the manufacture of domestic hollow ware; in machine fitting; in the manufacture of pearl buttons, etc., and thus, indirectly all these interests were concerned in the settlement of the question.

It is stated that the plant in question is the only one of its kind in the world, and that the decision that the Supreme Court has rendered will suppress the entire industry.

Evidently the Supreme Court took the same view of the case as did the Electric Smelting & Aluminum Company, which called the attention of the Court to the fact that the patents granted to Cowles were the first granted anywhere in the world for incandescent electric smelting: that is, smelting in which the heat of a resistance material rendered incandescent by the passage of an electric current, in distinction from the heat generated by an electric arc, hence the term "incandescent electric smelting." They also claim that there was no invention of carborundum by Mr. Acheson, but that he simply found out, the real composition was of the material which the Cowles brothers had discovered years before, and which had been described by them at various times through the public press; because they abandoned a further pursuit of the process for others that they deemed of more commercial value does not militate against the priority of their patent, nor could a play upon words be allowed to result in the destruction of the substantial rights which they held.

Again the statement of the Carborundum Company that so many interests would be injured, would seem to be refuted by the fact that all of the manufacturing concerns obtaining their power from the Niagara Falls Company and in other localities, are obtaining their results as licensees of the Cowles Process, one of the firms alone renting 14,000 electrical horsepower per day from the company named.

The statement of its commercial import has also been challenged, by a resumé of the abrasives used in the United States during 1899, of which carborundum amounted to 850 tons. For abrasive purposes, 735 tons; natural abrasives, more than 20,000 tons; other artificial abrasives 337 tons; natural grindstones, whetstones, etc., to a value of $911,984.

* * *

Electric Guns. For several years inventors have been at work, both in this country and abroad, trying to devise some means of applying electricity to the firing of cannon. About two years ago a resident of Washington thought he had hit upon the solution of the problem, and suggested firing shell through a solenoid by means of an electric current and a complicated system of automatic switches. Still more recently a resident of New Orleans brought out an electric gun—the model of which, by the way, was about the size of a lead-pencil—for which great things were hoped, while only a week or two ago advices from England stated that a gentleman living at Newcastle had invented an electric quick-firing gun with "startling features." This gun, which is primarily intended for naval warfare, is based, so it is claimed, upon entirely new features. The base of the gun is conical, with two vertical supports, which carry the centrifugal mechanism, with a small electric motor fixed on the side. This motor would receive its power from the electro-generating plant, which forms a portion of the equipment of every warship. The current may be transmitted to the fighting tops, or any other desirable part of the vessel. The power thus transmitted to the motor causes the gun disk to revolve at a high velocity. The shots are absorbed by the gun automatically and by the movement of a small lever. The inventor states that the gun can fire anything up to over 3,000 shots per minute, with a muzzle velocity approaching 2,000 feet per second. These shots are impelled without explosives by centrifugal motion; consequently, during process of firing there is an absence of both noise and gun recoil. The gun can also be placed upon a light carriage, or motor platform for field purposes, the power being generated by a small oil-motor mounted on a light gun-carriage with generative electric machine, thus supplying any number of guns, over any area, from the one reservoir. The gun is worked by two men, who are effectually protected behind a light shield. It will fire round a complete circle, and possesses a vertical range of 90 deg. It stands five feet in height and weighs about 6 cwt.

We have no desire to decry things electrical, but in our opinion it will be some time before a real electrically operated gun is brought out, and when it does arrive it will not be worked on the lines laid down by some of the recent inventors.

Notes and Comments on Various Topics.

THE New York Telephone Company is putting in 800 special telephones for election purposes.

THE splendor of the electrical illuminations and decorations of the Parliament buildings at Ottawa during the Queen's jubilee celebration three years ago, will be surpassed in extent and magnificence on the occasion of the return of the Ottawa soldiers from South Africa, whose home-coming is now daily expected. The Government, in addition to the city's decorations, will spend over $10,000 in the electrical display on the Parliament buildings, and which is expected to be the most splendid ever given in Canada.

ALL of the down-town conduits of the system of electric subways in the City of Baltimore will be completed, and the wires now overhead placed in the ducts, by January 15, according to the commission in charge of the work. The companies now using over-head wires will be notified by letter and will be charged a nominal sum for the use of the ducts. Leases will extend for periods of six months, and may be abandoned on six months' notice to the city.

Electrical men will have a separate division in the sound money parade, which will take place in New York City on November 3. In 1896 the electrical contingent was split up, most of it being in the metals and machinery division. From present indications no less than 3,000 marchers will be in line from the electrical industries,

The disastrous fire and explosions in the drug house of Tarrant & Co., on the northwest corner of Warren and Washington streets of this city, which occurred at noon on October 29, and through which over 100 persons lost their lives, destroyed not only a portion of the Ninth avenue elevated structure, but also the up-State wires of the Western Union Telegraph Company. Over one million dollars' worth of damage was done, to say nothing of the appalling loss of life, all through the proper authorities allowing a firm in the heart of the community to store an excessive amount of explosives. If any other drug firm in the city is carrying a large stock of similar goods, they should be speedily made to transport them out into the country.

A suburban electric street car-line in St. Louis, Mo., has fitted one of its cars with a telephone for trial, says the "Railway and Engineering Review." The instrument is placed in the rear of each car, the negative wire being connected permanently through the wheels to the rail and the positive wire being fitted with a simple device resembling a jointed fishing-pole by which connection is secured with a private overhead wire paralleling the trolley.

Vice-Consul Harrison, at Asuncion, says that the Paraguay Development Company, incorporated with a capital stock of $500,000, under New Jersey laws with headquarters there has been granted by the Paraguayan Government a concession to light the City of Asuncion and to run tram cars by electric power.

The question of the utilization of the waterfalls in Victoria for the generation of electrical energy having been raised, Mr. Jas. Stirling, a geologist of the British Government, has in his report for March given a list of the waterfalls which have come under the notice of the officers of the Geological Survey. The list gives the name of the falls, the locality in which it is situated, and the height of the fall. The fall having the greatest drop is the Yarra Fall, which has a drop of about 1,000 feet. The next highest fall is one on the Dondangadale River, which drops some 400 feet. The height of the other falls ranges between 300 feet and 28 feet. Some of the streams are liable to cease running during very hot periods, but the majority of the streams are perennial. Several of the water-supply weirs could, says the London "Electrical Engineer," well be used to store water for the generation of electricity, and one of them—the Goulburn weir—actually is used to generate electricity for lighting purposes.

News from Tacoma, Wash., states that steamers in from St. Michael bring word that the United States telegraph system in the Yukon will be completed from Nome to Tanana by Christmas. The line from Dawson northward to Eagle on the American side will be finished shortly. The line between Dawson and the outside is now about completed. So by Christmas the stretch between Eagle and Tanana alone will remain to be built to connect Nome with the world at large. That stretch is 800 miles. The telegraph constructors of the United States are scattered along the Yukon from Eagle to Nulato, at the point of beginning of the over-land cut-off to Nome, in numerous crews.

Among the novelties promised at the Automobile Show, to be held in this city from November 3 to 10, is to be an artificial hill over which the automobiles will climb.

Acetylene gas has again been heard from. On October 28 a minister of the Gospel in Austin, Ill., was adjusting an acetylene gas generator in his church when it exploded, inflicting injuries which it is thought may prove fatal. The church was damaged to the extent of $3,000.

A deputation from Ottawa has waited upon the Ontario Government for the purpose of obtaining authority of the Government to use the power in the Ottawa River of the rapids at Britannia. The company is known as the Metropolitan Electric Company, and it is said that it intends establishing a pulp mill to be run by electric power.

The new Russian battleship Retvizan was launched at Cramps' ship yard at Philadelphia on October 23. Very elaborate arrangements have been made for insuring a continuous supply of ammunition to the rapid-firing guns. The turrets will be operated by electricity; in fact, many of the auxiliary machines usually operated by steam will on this vessel be driven by electricity.

The development of the use of electricity during the past few years has created a demand for mica as an insulating material. Much of the small-sized mica, formerly of little value, if not altogether unsalable, now finds a market among electrical manufacturers. Part of this small mica is reported in the sheet-mica products, and as it sells for much less than the larger sizes, which are used in the manufacture of heating stoves, lamp-chimneys, etc., it has the effect of making an apparent decline in values. On the other hand, part of the small-sized sheet-mica used for electrical purposes is reported as scraps, and in this case causes an augmented value.

Great results are expected from a new discovery of a Mr. De Gall, inspector of forests at Lamur, France, according to a dispatch received at the State Department from Vice-Consul General Hanauer at Frankfort, Germany. The new invention is a method of producing a wood impervious to water and acids alike, and a perfect electrical non-conductor. That is accomplished by means of dry distillation and high pressure which prevents the escape of developing gases and reduces the wood to a hard body of the character of coal, yet without a trace of the organic structure of that mineral. This new body, though hard, can be shaped and polished at will.

Remarkable electrical disturbances are often produced by the salt storms from the plains along the high voltage line running from Provost, Utah, to Tintic. On account of the moisture in the air and the thick covering of the poles with salt, powerful discharges occur at frequent intervals: short circuits are momentarily caused; the lights dip, and sometimes the operation of the motors is interfered with. These discharges are usually of dazzling brilliancy and at times startling. The flames are said to reach a height of from six to eight feet, holding for a second or two, then break from one of the wires and die away. It is only when the arc is continuous between the wires that there is any interruption of the service. One flash which blew out the station fuses and caused a shut down held its place between the wires for five or six seconds, but most of the flashes cease almost on the instant of completing connection.

The penny-in-the-slot system of distributing gas through the poorer and artisan districts of London, England, has been so successful that attempts are now being made to supply the electric light in the same way. The vestry of Battersea has erected a large generator station which is nearly completed, and laid the necessary cables down in the roads. The fixtures are installed in the house free of cost to the customer, who simply pays for the amount of electricity he consumes. The profit derived from this method of distribution is sufficient to enable the authorities to recoup themselves for the initial cost of the installation of fittings in the houses.

The possibilities of some of the suburban electric street railroad lines as freight carriers are now being ascertained to some extent by the Washington, D. C., Traction and Electric Company. Mr. T. F. Alvey has been placed in charge of this department, which has been newly created. On two of the lines—that to Rockville and the eastern section of the Columbia road—a freight service has been established. As the entire undertaking is experimental, the details are being worked out according to the demands of the business. The importance of the territory traversed by these lines, especially as to the prospects of yielding a traffic of this nature, no doubt led to their selection by the company for the initial trial.

Electric railways are making rapid progress in Australia. In Sydney the Government is replacing section after section of the old steam railroad with the trolley wire. According to a communication from Sydney private enterprises in the electrical line are not idle. In Brisbane the tramway company is seeking powers to enlarge extensions, and in Melbourne the suburban authorities are proposing a trolley line connecting the suburbs with each other directly. As American engineering concerns in the electrical line are advantageously competing, in all probability a good share of the material, etc., needed will go from this country.

A special meeting of the board of directors of the Electrical Contractors' Association of New York State was held at Buffalo last week. The various associations were represented by their directors as follows: New York City by President Charles H. Endlity; Utica by W. H. Morton, of the firm of Johnson & Morton; Syracuse by President James Hilton, of Rodgers & Hilton; Rochester by Rudolph Schmidt, and Buffalo by J. C. Sterns. After the meeting the president of the Buffalo Electrical Contractors' Association, H. I. Sackett, together with its members, Messrs. Mann, Ford, Jones, Brehm and Wilhelm, met the delegates. The visitors were entertained at dinner after which two automobile 'buses furnished a very enjoyable ride. The whole party attended the theater and a supper followed.

COMPARISONS OF THE VARIOUS SYSTEMS OF ELECTRICAL DISTRIBUTION FOR STREET RAILWAYS.*

BY C. F. BANCROFT.

In preparing a paper on "Comparisons of the Various Systems of Electrical Distribution for Street Railways," the subject selected by the executive committee, I find that the conditions to be met in the numerous localities where the various systems are in use are so widely different, and each system so generally satisfactory, under certain conditions, and so completely unsatisfactory for meeting other conditions, that comparisons are altogether impossible, except, in a very general way.

There are six systems of electrical distribution for street railways at present in more or less general use.

First, what may be called the standard 500-volt continuous current system, where the current is generated at from 500 to 600 volts and delivered direct to the car motors, usually by means of a feed-wire and a trolley, third rail or underground conduit.

Second, what may be called the alternating direct current system, where the power is generated as alternating current, usually at high voltages of from 5,000 to 15,000 volts, and transmitted to sub-stations, where the voltage is usually reduced by means of static transformers, transformed into direct current by rotary converters, and delivered to the lines at about 500 volts continuous current.

Third, the "booster " system, where the current is generated usually at about 550 volts and where, by means of an auxiliary generator, usually series wound, called a "booster," additional voltage is generated and compensates for that lost on the line.

Fourth, the so-called three-wire system, where the current is generated at about 1,000 volts, usually by means of two 500-volt generators connected in series, and is delivered to two motors or two groups of motors in series.

Fifth, the alternating current system, where the power is generated as alternating current, usually at high voltage, and transformed down to about 500 volts at the trolley wires by means of static transformers, which may be located on the poles supporting the feed-wire and trolleys, the cars being equipped with alternating current motors.

Sixth, the storage battery system, where the batteries are carried on the car and charged at the power house or at special points on the line. Storage batteries can also be used to advantage in connection with any of the above systems under certain conditions, and in fact combinations can be made of any or all of the above systems.

For any given conditions as to speed, traffic and length of line, some one the above systems is likely to be much better fitted and more efficient than any of the others; therefore, it seems to me that a comparison of the various systems can best be made by considering the particular conditions most favorable to each. In the distribution of power for street railways the result to be aimed at is usually the maintenance at variable loads of an approximately constant pressure of 500 volts on the trolley wire at a minimum total cost for power.

The cost of generating electric power under the same conditions, as regards fuel, depends to a great extent on the amount of power generated and the capacity of the generating apparatus with reference to the average output required. Under ordinary operative conditions, with the same power factor, that is, the same ratio of output to capacity, the cost of power per kilowatt hour from stations of less than 500 kilowatt capacity increases very rapidly as the station decreases in size. With from 500 to 1,500 kilowatt capacity, the cost of power per kilowatt hour decreases slowly as the size of the station increases. From 1,500 to 2,500 kilowatt capacity the cost per kilowatt hour decreases very little as the output increases, and above 2,500 kilowatt station capacity the cost of power per kilowatt hour becomes nearly uniform. This is due to the fact that in small plants the labor item is disproportionately large and the general efficiency less than in larger ones, while in plants of 1,500 kilowatt output and larger the cost of labor remains proportionately nearly the same as the plant increases in size. It follows from this that there is often very little or nothing to be gained from an economical standpoint by substituting one station of 5,000 kilowatt capacity for two of 2,500 kilowatt capacity each, provided the local conditions, as regards cost of coal, water, etc., are the same.

The system of distribution most suitable to a particular road, depends to a great extent on the location of the power station or stations and the nature of the load. It is always expensive to transmit power, the expense being either in interest on copper investment or in fuel or both, and, therefore, other things being equal, the location of the power station or stations should be as near the load or center of distribution as possible. The location of the station is, however, usually governed to a considerable extent by local conditions as regards cost of fuel, water and real estate.

On a large system, requiring an average output of 12,000 kilowatts, even though the load be distributed within a five mile radius of a practical station location, it will usually be found economical to generate this power at several smaller stations rather than at one large station, provided the conditions as regard cost of fuel, water, and real estate are about the same, as the cost of power station buildings and machinery per kilowatt of capacity and the cost of generating power per kilowatt hour, with a station of 5,000 kilowatt capacity, is about the same as at a station of 10,000 kilowatt capacity. The interest on the saving in cost of feed-wire by having several stations, each located near its load, would more than offset the slight saving in cost per kilowatt hour, due to the generation of power at one large station, and it also has the advantage that in case of fire or accident to one station, the other can usually be so interconnected as to temporarily carry the entire load, and thereby avoid much of the stoppage of traffic which would occur if the road was supplied entirely from one station.

For an example of what was called the first or standard 500 volt continuous current system of distribution, a city may be cited in which the street railway lines radiate west from the center of the city like the spokes of a half wheel, with a radius of about five miles. Instead of having one large station at the hub of the wheel, the road is supplied with power from seven stations, distributed throughout the system, having an aggregate capacity of over 26,000 kilowatts.

The generating and distributing system in use in one of our most densely populated cities may be taken as an example of the way in which the system of distribution adopted is governed by conditions outside of those indicated for the most economical generation and distribution of power to the car motors. Although this system is compact and will probably require an average station output of over 30,000 kilowatts, which it would seem to the outside engineer could be more economically distributed and almost as economically generated at several stations, the street railway company is installing a high-tension alternating direct current system of distribution with a main station of 45,000 kilowatts ultimate capacity, and five rotary converter sub-stations of from 3,000 to 6,000 kilowatts capacity each. It is probable in this case that the location of the power station and the system of distribution was governed almost entirely by the great cost of real estate at points suitable for separate power stations.

It frequently happens that several miles distant from a street railway system much cheaper power is obtainable than at or near the center of the system. This may be due to an available water power, or to a difference in the cost of fuel, etc., at the two points. In cases of this kind the second, or what may be called the alternating direct current system, is usually the most applicable. To transmit power at 500 volts in any quantity from a distance of ten miles, or even less, is very expensive, owing to the large amount of copper required and the great loss. For instance, to deliver 500 amperes at ten miles distance will require about one hundred and fifty tons of copper, allowing a loss of about 30 per cent. in the line. This same amount of power could be transmitted at 5,000 volts by an alternating direct current system with about five tons of copper and with a loss of less than 10 per cent. in the line.

The weight of copper required to transmit power a given distance, other things being equal, is inversely as the square of the voltage, that is so say, if it takes 100 pounds of copper to transmit a certain amount of power a given distance at 500 volts, it will only take 25 pounds of copper to transmit the same amount of power the same distance with the same loss at 1,000 volts. It is owing to this fact that the alternating direct current system is so applicable where the power has to be transmitted for any considerable distance, as it allows of the use of very high voltages on the line, 10,000 volts or more being in general use, which by means of transformers and rotary converters can be reduced to 500 volts direct current for the trolley wire at points where the power is required. For an example of this system of distribution a street railway system may be cited which derives its power from a water fall. Here the power is generated at a pressure of 2,200 volts and is stepped up to 11,000 volts for the line. About 6,000 hp. is transmitted at this voltage for a distance of about twenty-one miles. The voltage is then reduced to 500 volts direct current, by means of static transformers and rotary converters at five sub-stations, located at or near the points where the power is required,

The third system mentioned, the "booster" system, is chiefly applicable on lines where there is a light average load, but where for short periods an extra heavy load has to be taken care of. It would seldom be economical to supply an entire road with power by means of a booster system, as the greater part

*Paper read at the Nineteenth Annual Meeting of the American Street Railway Association held at Kansas City, Mo., October 16-19, 1900.

Digitized by Google

of the power generated by the booster represents wasted energy, which is usually generated in an extravagant way, as the power required to drive the booster varies as the square of the current in the feeder, that is to say, if it requires 50 hp. to drive the booster with a load of 100 amperes, it will require 200 hp. to drive it if the load is increased to 200 amperes. Line losses which necessitate the continuous waste of more energy than could be compensated for by an ordinary compound wound railway generator are seldom economical, even on a portion of a system, but there are many cases where there is sufficient copper installed to take care of the average load economically, but where for a short time each day, or for a few weeks in the year, owing to local conditions, the traffic is very unusually heavy.

In cases like the above, where the heavy traffic is of short duration, a well designed booster system may save a large investment in copper at a total cost of much less than would be required to pay the interest on the copper investment. For an example of this method of distribution I might cite a street railway company which supplies power to its own lines by means of a standard 500 volt direct current system, and which also supplies power to a smaller road about thirteen miles distant by means of a three-phase alternating current system, using 5,500 volts on the line. Here the booster system is used in connection with the high tension system. When it becomes necessary to repair the high tension line, it was found expensive and inconvenient to do the work between the hours of 12:00 midnight and 4:00 A. M., the only time when the power was off, and as it was not considered safe to work on the line when it was in operation, a booster system was arranged to supply power to the distant road for short periods at times of light load. A 200 kilowatt booster was installed at the generating stations and was designed to raise the voltage one volt per ampere of current. Switches were installed at the sub-stations so that the high tension line could be connected directly with the 500 volt feeders, some 8 miles from the generating station, and the booster was arranged so that it could be readily connected to the high tension feeders.

When it was necessary to replace broken insulators or make other repairs on the line the attendants were notified at the generating station and at the sub-stations, and at a prearranged signal, made by varying the voltage on the line, the alternators were thrown out, and the booster thrown on in such a way that the power was only off from the trolley wire for a fraction of a minute. It was thus found quite practicable to make repairs on the line while the booster was in operation, and the system proved very satisfactory for supplying power at times of light load, while repairs were being made; the load on the booster frequently running as high as 500 amperes, at which time the voltage generated by the booster was about 500, which in addition to the 575 volts of the direct current system gave 1,075 volts at the generating end of the line; the voltage at the sub-station averaging about 450. While it would have been very expensive to run this booster for any great length of time, for the short time it was used the total cost was much less than the interest on the copper investment required to build a duplicate line.

The fourth system mentioned, or three-wire system, is most applicable to double track lines, where one trolley is made positive and the other negative, there being about 1,000 volts potential difference between the two, the current flowing from the positive trolley wire through the car motors to the rail and from the rail through the car motors and the other track to the negative trolley. The track is usually cross-bound and also connected to the conductor or connecting the two generators which are operated in series in the station. This connection with the track forms the third wire and tends to equalize the voltage should there be more cars on one side of the system than on the other. This method of distribution is usually capable of saving from 20 to 40 per cent. in copper, according to the character of the track return. If well balanced, it also greatly reduces the electrolytic action on buried conductors, such as water pipes, etc., and it is most applicable where there are excessive track losses with fair opportunities for a balanced load.

There are few roads in this country using the three-wire system of distribution, although it is used almost universally by lighting companies. This is probably due to the complications introduced in railway systems by the high voltage, usually about 1,000 volts, between the trolley wire and feeders on different sides of the system and the difficulty of balancing the load. The saving in copper, while not as great as in the three-wire lighting system, is still enough to warrant the extra complication, and under favorable conditions may prove very valuable.

I am only familiar with one example of this system of distribution. In this case there is very heavy traffic over a double track line to a park, about six miles from the power station. It was found impossible to handle the increased traffic on the ordinary 500 volt system with the existing feedwire. By re-insulating the line and operating it on the three-wire system, the efficiency of the distributing system was very much improved and they were enabled to easily handle the increased traffic with the existing feedwire.

The fifth system mentioned, or the alternating current system, is practically untried in this country. It seems peculiarly adapted to lines having long runs at uniform speed with few stops, such as lines connecting cities, rather than for ordinary street railway service. The alternating current motors at present in general use are of the polyphase type, and require at least three working conductors, which is a serious objection in many cases for railway work, as it necessitates the use of two trolley wires in addition to the track as conductors. The disadvantages of this system appear to be the necessity for at least two trolley wires and the probable difficulty in building alternating current motors suitable for railway work which will have a good power factor.

The main advantage of the alternating current system is the possibility of feeding lines with stationary transformers which need no supervision, but which can be considered simply as a part of the feeder, thereby multiplying many times the length of line which can economically be supplied with power from one station. The alternating current motor also has the advantage of running at fairly constant speed independent of the load. It will not race going down hill if the power is left on, but will return power to the line, nor will it slow down much in going up hill. There are four or five railway companies using this system, and judging from the reports that appear from time to time in the railway journals it is giving very satisfactory results.

The sixth system referred to, or storage battery system, is decidedly more expensive than the usual methods of electrical distribution owing to the great first cost and the short life of the batteries. Lead is at present the only metal capable of resisting the attacks of sulphuric acid, and modern batteries consist largely of lead, which is very undesirable from a mechanical point of view and is very heavy, so that unless the present type of storage battery is substantially improved, this system is only likely to be used where other systems are not practicable owing to peculiar local conditions or restrictions. The storage battery, however, has a large field in connection with the other systems of electrical distribution for street railways, and under favorable conditions may considerably increase the station capacity and reduce the fuel consumption; and when used on the line may greatly improve the regulation and increase the copper efficiency.

From this brief outline of the various systems it will be seen that each has its peculiar advantages and that no one is suitable under all conditions. It will generally be found that where the traffic is heavy and the distance short, the standard 500 volt system is most applicable. For suburban work, where the distances are greater and the traffic less congested or where it is necessary to transmit the power for some distance, the polyphase alternating direct current system will usually be found more economical. In special cases, where for short periods of time an unusually large amount of power is required, the "booster" system will often prove very valuable, while for high speed, long-distance, interurban work the three-phase alternating current system may be attractive. The cars on this system however, would have the great disadvantage of not being able to run over the ordinary direct current street railway lines.

There can be no general rule given that will determine the most advantageous system of distribution to use under the varying conditions to be met in street railway work. Each case must be considered as a separate problem and that method selected which will best meet the peculiar conditions involved.

SOME INTERESTING FAULTS MET WITH IN CABLE MANUFACTURE.*

BY J. WRIGHT.

A fault, whatever its nature, is at all times abhorrent to the electrician in charge of a network, but becomes more or less an object of interest when its position has been correctly localized, from the point of view indicated by cause, effect, and future prevention. In no branch of the profession are a greater variety of faults and their causes to be met with than in that of cable manufacture pure and simple; such faults arising, in process of manufacture from carelessness on the part of the operatives, inadaptability of machinery to a specific purpose, or other unforeseen circumstances.

It is with the object of interesting the reader, and at the same time exhibiting the difficulties which the much-maligned and long suffering manufacturer has perforce to contend with, that the following paragaphs have been written.

In rubber and gutta-percha insulated wires

*From the "Electrical Review," London.

Digitized by Google

and cables, the faults most commonly met with are due to foreign matter and impurities in the insulating medium. Both rubber and gutta-percha, in the raw state, are essentially impure, owing to the local conditions governing their collection. For this reason they have perforce to undergo an exhaustive series of purifying processes before their final application to the cable or wire which they are intended to insulate, such as repeated washings in several waters, mastication, sieving through a gradually decreasing mesh, etc., but despite these precautions, impurities will often find their way into the final result with disastrous effect. Cleanliness and care are essential in cable manufacture; the presence of any foreign matter, especially in gutta-percha, will make itself evident in the final tests, however slight its proportion to the total mass of insulation. Such faults as these, due to impurities, are seldom found by inspection, to a rigorous system of which most core is subjected in its unfinished state, with the single exception of gutta-percha core, which, by its homogeneity of texture and monotone tint, readily lends itself to a minute visual inspection, which, with practice and experience as exemplified in some of the old hands to the trade, serves to

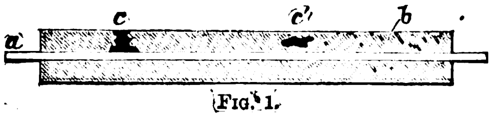

Fig. 1.

Fig. 2.

eradicate most of the faults due to this cause. The remainder have to be localized electrically to which end there are many systems, all more or less suitable according to local circumstances and which lend themselves, in the majority of cases, to actual spot localization.

Among the many impurities which find their way into rubber and gutta-percha compounds are wood, fiber, dirt, splinters of metal, mineral matter, etc., all of which, by their presence in the mass of the insulating sheath, tend to reduce its thickness, and, in many cases, form a direct conducting path from the conductor proper to the exterior of the core. The magnified appearance of a fault of this nature is represented in Fig. 1, where *a* is the conductor, *b* the insulation and *c* the impurity causing the fault. In the example shown, the foreign matter, such as a fragment of wood, for example, is represented as forming a direct path from the conductor. A less prominent case is denoted at c^1, where the impurity is totally imbedded in the insulating sheath; this would, in all probability, not become apparent as a decisive fault, but rather make itself felt in a local reduction of the insulation resistance, owing to the lesser thickness of the otherwise uniform insulating sheath.

Now, as to how these impurities find their way into the insulating medium:—Ordinary dirt and impurities may be generally accounted for by insufficient washing and mastication; but minute splinters of wood, for instance, may be accounted for in a different way. The rubber, previous to its application to the conductor, is in the form of rolls of sheet, mounted on a cylindrical wooden mandrel in a lathe, for the purpose of cutting it by means of a knife tool into rubber tape of varying widths, in which condition it is applied to the cable or wire; if the tool be advanced too deeply into the thickness of the roll its extremity reaches the wooden core, and in all probability cuts it slightly, the subsequent splinters, if the wood be soft, being commingled with the last layer of rubber. This cause of fault has been eradicated in many factories by making the cores of hard wood and dispensing with the final 6 inches, or so, of rubber tape, when running through the machine, an additional safeguard being provided in the shape of a stop to limit the depth of penetration of the cutting tool.

Fragments of metal, copper, tin, etc., are frequently separated from the conductor itself in the following manner: The smaller sizes of strands and single wires generally are covered with rubber by compression, i. e., the conductors, together with two strips of rubber one above and the other below, are passed between pairs of accurately turned hard steel rolls, which are grooved semi-circularly, such that at the point or line where they meet and revolve against one another, they form a complete circle equal in area to the cross-section of the finished or rubber-coated core. The seam or junction is secured to perfection by that property of freshly-cut rubber surfaces known as cohesion. Now, it is obvious that to secure centrality of the conductor it must pass absolutely through the center of the circle formed by the groove in two rolls; this is generally secured by passing it through frictionless guides, and also by maintaining the wire or strand taut between the limits of the machine by means of tension devices. Notwithstanding these precautions, it frequently happens in the case of stubborn wires or strands, such as 1/12 or 7/14 for example, that a slight kink in the bare conductor will pass between the rolls unnoticed, the existing tension being insufficient to straighten it. In a mild case, this usually results in throwing the conductor out of the center, as represented end-on in Fig. 2, such that the insulation is very thin on one side and correspondingly thick on the other, which has an obviously deleterious effect upon the ultimate insulation resistance of the core.

In extreme cases, however, as with a bad kink, the periphery of the conductor itself passes at one point between the contact surfaces of the rolls, and is squeezed out into a species of metal fin, surrounded on all sides by rubber, but usually with its extreme edge exposed, as represented in longitudinal section by Fig. 3, where *a* represents the conductor as before, *b* the insulation, and *c* the fault.

Fibrous impurities, such as cotton, jute, etc., frequently occur, and, absorbing moisture by capillary attraction, provide direct conducting paths from the conductor to the exterior.

Another frequent cause of fault is the cohesive seam before alluded to, which requires to be subjected to perfect compression by two meeting surfaces to ensure its satisfactory production. If the rolls by which it is produced be not accurately surfaced and re-turned from time to time, the wear and tear consequent on frequent and daily use causes them to become untrue, with the result that they do not actually meet, and the subsequent seam is in consequence imperfect, and tends to open again at that point instead of becoming, as in the case of a perfect seam, homogeneous with the remainder of the insulating sheathing.

This cause may be practically eliminated by systematic inspection and overhauling of rolls, as now adopted in the leading cable factories.

A very frequent cause of local weakness in insulation is the absence of pure rubber at certain points along the core. The pure rubber, which is the first coating applied to the conductor in vulcaized rubber-covered cables and wires, is, especially in the smaller sizes, responsible for a considerable percentage of the ultimate insulation resistance, and, if conspicuous by its absence, tends to lower the final megohmic result obtained. This absence of the coating is explained as follows: The pure rubber takes the form of a very thin coat applied spirally to the conductor under tension, i. e., it is stretched in position, each turn or lap overlapping the last by an amount sufficient to produce a perfect homogeneous joint by the aforementioned property of cohesion. If the rubber should give way at any point through inherent weakness or careless jointing, its natural elasticity causes it to run back for a short distance, and so leave the conductor exposed. A bare portion of the conductor exposed in this manner may pass over unnoticed by the attendant, and receive its subsequent coating of compound rubber, which hides the original fault until it is exposed by the subsequent electrical tests. For this reason, what is

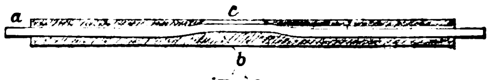

Fig. 3.

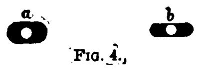

Fig. 4.

Fig. 5.

known as a "double lap" of pure rubber, though slightly more expensive in prime cost, gives much better results, in that any spaces left by the first coating are almost invariably covered by the second layer. This cause of fault has now been almost entirely removed by a rigid system of visual inspection of the unfinished core both entering and leaving the machine.

A very common manufacturing fault met with in vulcanized rubber-covered cables is that caused by a flattening of the insulating sheath due to excessive pressure while in a plastic state. Most compound rubbers before vulcanization are more or less of the consistency of putty, and, consequently, if subjected to any excessive weight or pressure, tend to flatten and lose their circular conformation. In order to undergo the process of vulcanization, the taped core is wound on cylindrical metal drums, which are then placed in the vulcanizing receiver. If an excessive length of core, running into several layers, be wound on these drums, the upper layers tend to press and contract on the underneath ones, thereby producing a flattening of the insulation, which —the rubber being then in a plastic state—becomes permanent, and, in extreme cases, causes the conductor to become exposed by sinkage through the surrounding rubber. Two faults of this description are represented in transverse section in Fig. 4, *a* being a mild case, and *b* an extreme one.

The taping, previous to vulcanization, is also frequently responsible for certain faults, of which the following are typical specimens: The "proofed" tape is applied spirally to the ruber-covered core under mild tension from a rapidly rotating "head." The tension is regulated by a nut and friction washer on the bobbin spindle; and if this be too tightly adjusted it causes the tape to draw in at its edges, and,

Digitized by Google

by excessive pressure, cut into the surface of the plastic unvulcanized rubber, producing a fault, illustrated to a slightly magnified degree in longitudinal section by Fig. 5.

A second taping fault which the writer has met with was due to the jointing of the tape, where one bobbin ran out and another started. This jointing is sometimes effected by the application of a slight touch of pure rubber solution, or, in other cases, by hammering the two "proofed" surfaces together on a flat base, and trusting to cohesion to secure the joint. The fault under consideration was caused by the former method, in which a somewhat liquid solution had evidently been employed to excess; the overplus of naphtha, or other solvent, had in this case dissolved a large portion of the rubber immediately beneath the tape joint, and thereby pitted the insulation in such a manner as to render it defective. Similar faults were experienced in this particular length of core at almost every tape joint.

Another result of tight taping is what is technically known as "spewing" of the rubber, which consists in the plastic rubber forcing its way under pressure of the encircling tape

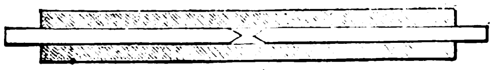

FIG. 6.

FIG. 7.

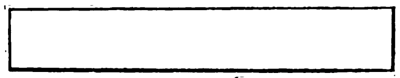

FIG. 8.

through the interstices of the fabric, and assuming a bead-like formation on the exterior surface of the core; in this manner the true thickness of the insulation is diminished, and its insulating qualities thereby impaired.

Broken wires and strands, especially in the smaller sizes, are a constantly recurring source of trouble in cable manufacture, mainly owing to the fact that almost all cable machinery is started and stopped on the "fast" and "loose" pulley system, a very erroneous one, under the circumstances, for this class of work. Almost all cable machinery, whether rubber-covering, taping, braiding, compounding, or armoring and serving, has a tension device of some kind, acting more or less directly on the cable attached to it, and the result of a sudden start on a hitherto stationary conductor can be better imagined than described. Numerous faults arise from this cause alone, large cables, having a conductor diameter of .5 inch or even more, being broken in this manner. In the case of small single wires, provided the shock be not very great, the broken extremities of the conductor are frequently held in intermittent contact by the inherent elasticity of the encircling rubber, which remains undamaged, thus giving greater trouble in localization. The sectional appearance of a fault of this description is represented by Fig. 6.

Breaks in small single wires are often the result of overheating or burning in jointing, the copper at that point being thereby rendered "short" or brittle. For a similar reason the use of an acid flux in soldering electrical conductors is tabooed, as the smallest trace of such a flux remaining on the finished joint will in time exercise a corrosive action on the metal thereof, tending in most cases to ultimate severance of the conductor, or, in any case, to the introduction of a high electrical resistance at that point.

Another form of fault which is occasionally met with in stranded conductors, especially when the conductor is of that particular quality technically known as "hard drawn," is that due to what is known as "bird caging," which consists in a general tendency on the part of the component wires to unstrand, causing them to bulge out of their normal position and engulf the surrounding insulation. The appearance of a normal and "bird-caged" strand of seven wires is represented in transverse section by *a* and *b*, Fig. 7.

Lead sheathing, which is so universally adopted as a mechanical protection for electric cables and wires, is responsible for several faults. In fiber-insulated cables, the imperviousness of the lead sheathing is the only guarantee of quality, in that a pinhole, extending through the thickness of the sheathing, will ultimately develop into a fault by the entry of moisture at that point. Such pinholes and flaws are frequently caused by the presence of minute quantities of red lead in the bulk of the metal, which passes through the press and ultimately presents the appearance of a small crack or flaw in the surface of the lead as represented in Fig. 8.

Other manufacturing faults in the lead sheathing process result from over-heating of the metal, etc., and frequently lead to the destruction of the actual insulating material while passing through the press.

The above-mentioned faults represent only a small percentage of the many which arise in process of cable manufacture, and are the result of observation on the part of the writer at some of the leading cable factories. They are in many cases responsible for the delay in execution and delivery of cable contracts, being, in the majority of cases, unforeseen, or due to carelessness on the part of the operatives. In some cases the fault lies with the customer, who, for the sake of a few shillings, will insist on a large single conductor or other erratic specification of his own personal conception instead of accepting the standard designs which have stood the test of time. In the writer's opinion 1/14 is the safe limit for a single conductor; after that size is passed, stranded conductors should invariably be employed; they are more flexible, easier to manipulate, and carry a more reliable guarantee of quality than a single conductor of equivalent cross section.

Bacterial Light.

Speaking of the uses which are now being found for various micro-organizms, the "Lancet" mentions as a thing to be cultivated that kind of bacteria which emits a phosphorescent light. The phosphorescent microbe, it states, if properly fed, will grow and multiply enormously, emitting during its development a strange phosphorescent light. In the past this light has been looked upon as indicating phosphorus in the neighborhood, but in a large number of cases it is not due to any chemical change, but to countless micro-organizms. In the case of the phosphorescence of the sea this is so, and in this case the phosphorescence is best when the sea is disturbed and the maximum of light is emitted from the crest of a short rapid wave, or in the foam produced by the water striking the shore.

DOUBLE TRUCK CARS—HOW TO CONSTRUCT AND EQUIP THEM TO OBTAIN MAXIMUM EFFICIENCY WITH MINIMUM COST OF MAINTENANCE.*

BY N. H. HEFT.

In order to prepare a paper which would be of any value to members of this Association, it was necessary to learn the conditions governing the operation of double truck cars on different systems. The conditions under which cars are operated vary to such an extent that it is impossible to construct and equip a car that can be operated with equal economy on each system.

In order to keep within the time allowed by the committee, and the more readily to convey to the members the writer's opinion as to the most desirable double truck car, the subject matter will be taken up under the following divisions: 1st, Trucks; 2d, Electric Motors; 3d, Double Truck Car Body and Equipment.

TRUCKS.

The double truck for use on street railways has not received the attention it merits. These trucks have been constructed along the lines of the single truck, and to meet the varied views of railway managements.

One has only to observe the different styles of trucks now in use to find how at variance have been their views.

The 55 years' experience of the steam railroad in the development of the double truck now used by them should be a warrant to the street railway managements in adopting only trucks that conform to the lines used by these roads; the diameter of wheels, with the tread and depth of flange should be changed only where conditions prevent using the Master Car Builders' standard.

The truck dealt with is a double truck, designed along steam railway lines to meet the varied condition of street railway service. In the plan of this truck, it has been the aim of the designer to include all known good features of the present street railway truck, and to add improvements of value. This truck is constructed with a minimum number of parts consistent with safety, strength, accessibility, lightness and cost of maintenance.

In giving a brief description of the truck referred to it will not be necessary to mention the wheels further than to say that they are cast chilled, 33 inches in diameter with a 3 inch tread, and 1 inch flange, formed to fit the modern rail, weight 380 pounds.

The axles are of forged steel, high in carbon, with a 2-inch hole bored through the entire length. The key seat at the gear wheel-fit is cut above the line of motor bearings and journals, in order not to weaken the axle.

The oil boxes are constructed so that the journal brasses may be readily removed with dust guard placed in position from the underside of box. An extra guard is placed from the same side and where it will retain the oil at the highest point.

The journal brasses and boxes are finished in such a manner as to obtain the full journal bearing under all conditions.

The side frames are made from two ⅝-inch steel plates, thus allowing the main equalizer to be supported between the two frames on long spiral springs. With this arrangement,

* Paper read before the Nineteenth Annual Meeting of the American Street Railway Association held at Kansas City, Mo., October 16-19, 1900.

Digitized by Google

the bar can be removed for repairs without in any way taking the truck apart. This form of frame allows the greatest accessibility to all parts, and the use of the extended equalizer bars, gives extended spring movement, with a perfect slide movement on curves and at low places in the track, minimizing the blow to the car body, rail joints and special work and reducing the cost of maintenance of track and equipment. The side frame is so strongly constructed at points where the transom joins the frame that it is not necessary to continue frame around end and connect with the other side of frame to keep the truck in alignment. This also allows the placing of the truck near the end of the car body without coming in contact with the steps.

The brake is placed on the inside of the wheel, without using a brake beam. This position insures the most positive action, with either hand or power and independent braking on each wheel. The wheel base, 5 feet, 6 inches, allows the motors to be suspended between axles and transoms.

MOTORS.

The writer, having had experience with heavy and light motors, mounted with two motors on one truck, the other truck being an idle or trail truck, as well as with one motor on each truck, has found that, while greater efficiency is shown with the latter method, the two motors mounted on one truck, show a saving in labor, first cost of the trail truck, with less cost for maintenance.

Maximum efficiency, with minimum cost of maintenance, with both heavy and light motors has been obtained by mounting two motors on each truck, making a four motor equipment. With this form of equipment, higher speed and quicker acceleration are obtained with less power of consumption, both in the average and total for the whole trip.

After an experience extending from the time that the first railway motor was constructed, the writer knows of no mechanical apparatus in which the development has been so rapid and the point of perfection so nearly attained. Yet the future promises even greater development, both in the direct and alternating current motors. With the great corps of engineers employed by our large manufacturing concerns, working with the men who are operating these motors and constantly suggesting and demanding improvements, the ideal commercial car equipment will be developed.

The writer desires to call the attention of electrical and mechanical engineers to improving ventilation, increased copper, insulation, bearings, hollow armature shaft, decreased armature speed and gearless motors.

The controllers have not, as far as space and weight are concerned, kept pace with the motors. This part of the apparatus should receive the attention of the best talent of our manufacturing companies. The four motor controllers, in their present form, are large, cumbersome affairs, placed in that portion of the car body where it is inconvenient and expensive to support. A more satisfactory controller can be produced by using a small pilot controller placed on the platform, with some developed form of main controller underneath the car body.

DOUBLE TRUCK CARS AND EQUIPMENT.

From information furnished by operating department and personal observation, the writer is led to believe the following dimensions be most desirable: Length over all, 40 to 50 feet; width over all, 7 feet 6 inches to 8 feet 8 inches.

With the increasing demand from the traveling public for the extension of present systems to suburban districts with a more frequent service and increased speed, also the construction of long interurban lines, the present managements, to meet this demand are turning to the double truck car constructed along the lines of the steam railroad coach.

A double truck car the writer believes will become justly popular. This car combines the largest number of good features and is so constructed as to admit of placing the electrical equipment where it is accessible and less liable to come into contact with the truck or brake equipment.

The car body can be carried at the lowest point and the trucks placed near the end of the body. This car gives the maximum efficiency, durability, speed, safety, and seating capacity, attractiveness and ease and comfort to passengers, coupled with the minimum cost of construction and maintenance, and less dead weight per passenger, based on seating capacity.

The total weight is made up as follows:
Trucks, 3,970 pounds each.
Four motors, 2,385 pounds each.
Car body and equipment, 12,300 pounds.

Making a total weight of 29,780 pounds. This amount divided by 63 passengers gives a dead weight of 473 pounds per passenger. The cars of to-day show a dead weight, based on the seating capacity of full 750 to 1,100 pounds per passenger.

While the writer does not claim that the truck and car body described are perfect, yet he believes they are along lines that will become attractive to managers when taking up the cost of operation. Decreased cost of operation can only be obtained by purchasing equipments that are designed to perform a specific duty where all weights and speeds are known.

RAILWAY JOINTS AND TRACK.*

BY GEO. L. HALL.

Most managers of electric railway systems realize that good track is absolutely necessary. Not only is this fact forcibly illustrated by the increased wear and tear on the rails, joints, bonding, etc., where bad construction is used, but no small item is the damage to the rolling stock.

The best track that can be constructed is that which is absolutely free from any movements or impacts that can be prevented by the judicious use of the proper material and labor. Different conditions of heavy weights moving at high velocities must be dealt with, and any failure to provide accurate gauge, correct line and true surface will result in increased damage to both track and equipment. The structure must be adequate for the load and speed which it is expected to stand. The track is not primarily injured by the weight of the car, as weight in itself is an element of stability. Heavy weights moving at high speed striking irregularities of surface or line produce shocks and impacts which constantly multiply these defects and make the condition worse and worse. Therefore the management is justified in any additional outlay for labor and material that will reduce such irregularities in line or surface, and these facts should not be overlooked when considering first cost.

The general condition of track must not be judged altogether by how long it has been constructed or how lately worked over, but we must take into consideration the number of cars passing over, the kind of motive power used, and if in a city, the character of the street and street traffic.

There are many seemingly unimportant details that enter into the construction and maintenance of good track, and there is no part of a railway that requires more careful or painstaking observation and scientific methods of investigation in order to secure the desired results at a minimum cost. From experience the writer is of the opinion that too much attention cannot be given to accurate gauging. Many apparent imperfections in track are due entirely to irregularities of this kind. Especially is this the case on suburban lines and track constructed where there is no power to assist in holding it to line. No matter how true the surface and alignment may be, if the gauge is not accurate, poor riding track and more or less oscillation of the car will result.

As a rule, there are not many cross-overs or turnouts on electric railway lines, but a word about gauging at frogs would not be amiss. The proper alignment at such places is more important than it is generally considered to be. The practice of leaving the gauge a little wide at the frog-point should not be followed except where the conditions demand widening, and when such action is necessary the guard-rail distance should also be increased exactly as much as the gauge is widened. It is an error to suppose that the all-important point is to make the guard-rail distance exact, without regard as to whether or not the gauge is true. What should be kept in mind is the distance from the running-rail of the frog to that side of the guard-rail with which the wheel comes in contact. A frog may cause a noticeable lurch to the passing car when in exact position if the remainder of the track is too wide to gauge, either from its natural tendency to widen or from poor construction.

Some evidences of imperfect gauge are as follows: (1) When the frog receives a blow from the passing wheel or shows evidence of unnatural strain; (2) when near the end of the guard-rail there is an abrupt change from a badly-worn rail to a full head; (3) where there is a similar mark at either end of the frog; (4) when the guard-rail or the wing-rail of the frog is unnaturally worn and it is difficult to keep in proper position.

It is to be regretted that too often in the construction of electric railways it is necessary to close up the track before it is possible to work over the same after it has been in use for a short time. Especially does this refer to the surface and general condition of the joints. When the track material is new we have a solid riding surface, but this is largely due to the general strength and stiffness of the material. In a comparatively short time, varying with the traffic, the track does not ride as well as should be expected; the rails are slightly out of line and surface, the joints begin to bend, more or less play having developed; a tip appears near the rail end, and the joints are low. Without taking into consideration the damage to equipment and the use of labor which otherwise might be available for the constant improvement of the road, we are face to face with the question of repairs.

Theoretically and practically, everything that has to do with track work is subordinate to perfect line and surface. Work to exact

* Paper read before the Pennsylvania Street Railway Association, Oct. 10, 1900.

Digitized by Google

gauge, perfect level and true line, with correct spiking, thorough tamping, good drainage and other details essential to their preservation and one will be surprised at the good results that will follow.

One of the most important details of track work is the rail-joint, and under average conditions it is the weakest part of track construction. The amount of wear at the joint naturally depends on traffic. Once the fastenings begin to show failure they grow rapidly worse, and while weak, are not necessarily dangerous, but they cause a rough riding track, increase the wear of the rails and damage the rolling stock. Much of the ultimate deterioration of joints could be avoided if there was not a general tendency to purchase cheap material and keep down the cost, and if angle-bars are used proper attention should be paid to their design and general efficiency, especially as to bearing area. A joint is simply a fastening that holds together horizontally and vertically the ends of the two rails. In addition to being held up, the rail must also be held down. This fact is apparent from the manner in which angle-bars break. Investigation shows that 90 per cent. of broken angle-bars break from the top down, this being caused by the leverage of the rail, the shoulder ties acting as a fulcrum. This action is augmented by the irregularities in the wave motion. The remaining 10 per cent. of broken angle bars have been broken from the bottom up by suddenly applied loads. In a perfect joint the construction must be such as to make the joint as strong and as stiff as the rail; at the same time the elasticity must be sufficient to carry the wave motion uniformly along the track and allow no permanent set or deflection to take place, the joint returning to its proper position after each passing load.

One great difficulty with the joint question has been to decide which is the best design, other conditions being equal. The original outline of the angle-bar, together with some combination giving base support and adding strength, has shown the best results.

If the rail and joint are of about equal strength and flexibility the wear on the ends of the rail is true, while if the joint is stronger than the rail the wave motion is broken, and the wear at the joint is irregular. If the fastening is weaker than the rail the joint will become dipped and rail and joint kinked and worn.

Due allowance must be made for expansion and contraction, taking into consideration the fact that calculation of expansion and contraction must be based on the temperature of the rail itself, and not the temperature of the air at the time the rail is laid. Too much opening between rail ends is necessarily bad, and causes pounding. At the same time the elastic limit will not take care of great expansion and contraction.

It is estimated that the loss of energy caused by the resistance to traction offered by low joints is 2 hp. hours per mile of track. In addition to this there is the loss by wear and tear on cars, track material, etc. Therefore any increased outlay necessary to secure a good joint is more than balanced by the saving in the cost of maintaining the track and equipment.

The new pattern making and cabinet shop in course of erection at Scranton, Pa., is nearly completed. The machinery will be operated by electricity, and several motors have been ordered. A new panel planer will also be installed.

LONDON NOTES.

[From our London Correspondent.]

The Institution of Electrical Engineers.

The customary summer vacation of the English scientific societies has come to an end, and arrangements are now in a forward state for the 1900-1901 session. So far as the Institution of Electrical Engineers is concerned it has sometimes occurred to us that the meetings might well commence at an earlier date than has been usual. For instance last year the presidential address to open the session came off somewhere about the middle of November. This year there is to be a slight improvement in this respect, for on November 8, Prof. John Perry, F.R.S., opens the proceedings with his presidential address, and the distribution of last session's awards. Toward the end of the session "extra" meetings have to be held presumably to work off the congestion of papers.

The general expression of opinion is that under the present secretarial management new life has been infused into the Institution. The week's convention in Switzerland in 1899 was an excellent new feature, and this year's meeting with American electrical engineers in Paris will be long remembered. Next year, if all goes well, members of the English Institution will be off to Germany to inspect the numerous electrical works which they are so often informed are miles ahead of English enterprise. One occasionally hears the complaint that electrical engineers are too busy making money to expend time and attention upon the preparation of papers; there are, however, always plenty of good practical papers forthcoming, the principal trouble being that they are too lengthy. Many of those read last session were large enough to make a medium sized volume. This of course means that the electrical engineering journals—which already experience difficulty in furnishing even a mere historical outline record of electrical development from week to week—cannot give the papers that extensive circulation that they merit. For some years past ELECTRICITY has endeavored to place the more practical papers before its readers in America, but last session while the papers were of great interest their length prevented full justice being done to them. It seems that it would be by no means a bad idea, if the Institution were to continue its progressive policy, by the preparation of abstracts, a plan which is followed out with success by Institutions of lesser importance. This appears to us to be the more necessary at the present juncture for this reason; instead of the meetings being held at only London and Manchester, they are now arranged for Glasgow, Dublin, Newcastle-on-Tyne, and shortly at Birmingham. All these are branches under the council of the London Institution of Electrical Engineers and different papers will be read at each and all excepting when the London paper happens to be of exceptional interest when it may be read at all sections, if the local committees approve. Each section has its local president and secretary, and of course its presidential address. Altogether the coming session of the electrical societies looks as though it will be a very good one. Mr. W. G. McMillan, the secretary, has proved that the council was right in selecting him for the appointment, although his predecessor, Mr. F. H. Webb, served the Institution well and faithfully for many years.

The Central London Railway.

The continued great rush for traffic on this underground railway at certain hours of the day may be imagined, when we mention that there is a suggestion that two "tubes" should have been laid down for the "up," and two for the "down" line traffic, instead of only one. Of course in this there is exaggeration, but it is a fact that there is a good deal of grumbling on the part of the public; because the accommodation is insufficient, and the discomfort is great. The superior popularity of the "Tuppenny Tube," as the public now term it, has cast the Metropolitan steam sewer lines quite into the shade. These railways did not feel the competition so keenly at first, and for a time it appeared that they would not suffer materially, but when the end of the quarter came and season-tickets fell in, many of them were not renewed. Hence the Metropolitan lines are now quite down in the dumps, and unless events move more rapidly than they have done previously, even electrical equipment may not save the sinking ship.

How the Central London authorities propose to meet the heavy traffic is not quite clear at present. We hear that a two and a half minute service is introduced and that longer trains are to be run. It is amusing to read the numerous letters which appear in the newspapers from day to day regarding this railway. Even the "Times," notwithstanding its sober sides, is allowing letter after letter to appear, showing that amateur railway managers are rife and that they don't know of what they talk. Among the remarkable suggestions which these wiseacres have made are: In the morning between 8 and 10 use both tunnels for "up" trains, and in the evening between 5 and 7 use both tunnels for the "down" service! This needs no laboring to show its sheer absurdity!

Again reduce the demand to the limit of the supply by increasing the fares from 2d. to 6d.! Some of us do not forget the grumblings at the City and South London Railway when it charged 3d. instead of 2d. at the heavy traffic hours. How the press yelled at the thought of the man who could only afford his 2d. going to the wall while the rich (!) 3d. fare "passed by on the other side"! Then some writers have tried to create a scare by saying: "Supposing that a train stopped in the middle of a tunnel and the lights went out what should we all do then, poor things?" Sir Benjamin Baker no sooner silences these qualmish questionings than others come along and ask a hundred things. Really, we are sorry for Mr. Cunningham and the Central London management if it has to give heed to all that is published in the newspapers about its "tuppenny tube."

The Belle Isle Telegraph Line.

The superintendent of the Canadian Government Telegraphs reports that telegraphic communication, all the way down the north shore of the St. Lawrence to Belle Isle, will be completed this fall, though it will not be possible to complete the cable over to Belle Isle, owing to the loss, recently, of the Government steamer Newfield. The cable will, however, be put down next spring, and, in the meantime, an arrangement has been made by the Minister of Marine with the English Lloyds by which the Government operator at Belle Isle will receive signaled reports from vessels inward and outward bound and transmit these reports to Lloyds' agent at the city of Quebec.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

Mr. G. A. Burgess of Carleton Place, Ont., is forming a company to engage in the electric lighting and power business in that town. It is proposed to utilize the water power at Arklan.

The town council of Brockville, Ont., has taken over the electric light plant from the Light & Power Company in that town, in accordance with a by-law passed a few weeks ago. The civic commissioners subsequently proceeded to Plattsburg, N. Y., to inspect the electric plant there before deciding upon what steps to take to place the Brockville plant in a perfect, up-to-date condition.

The Electrical Construction Company of London, Ont., is asking for tenders for the erection of a new factory. It is the intention to have a three-story building, 40 x 100 feet. This company from a small concern has risen to great proportions, and forms another important addition to the manufacturing interests of the city of London.

One of the greatest pieces of work seen in Ottawa for some time is that now being prosecuted by the Ottawa Electric Railway Company in the erection of its new arc light station. The rock cutting has already proceeded to some 35 feet below the level and will be taken out to a much lower depth. The work of construction of the building will not be commenced before next spring.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended October 24:

Antwerp, 1 case, $12; 9 packages, $726; Athens, 13 cases, $276; Berlin, 11 cases, $326; Bordeaux, 33 boxes motors, $3,000; Bradford, 1 box, $39; Brazil, 102 packages, $22,994; Bremen, 3 cases, $831; Bristol, 56 packages, $8,340; British Guiana, 38 cases, $1,907; British West Indies, 4 packages, $124; British Possessions in Africa, 65 packages telephone poles, $2,800; 4 cases, $1,101; British East Indies, 1 package, $25; Brussels, 16 packages, $1,419; Central America, 252 packages, $1,792; 1 case motors, $50; Cologne, 51 packages, $10,657; Copenhagen, 1 case, $48; Cuba, 124 packages, $5,143; 3 packages cable, $171; 10,058 packages electric railway material, $113,605; Dutch East Indies, 11 cases, $259; Ecuador, 1 case, $20; Florence, 3 cases, $1,500; French Possessions in Africa, 14 cases, $2,163; Genoa, 1 case, $2; Glasgow, 3 cases, $146; Greenock, 114 packages electric motors, $1,524; 80 cases, $1,280; Havre, 9 boxes, $5,250; 108 packages, $6,181; Hamburg, 88 cases, $13,050; 16 packages, $569; Leeds, 9 cases, $671; Liverpool, 82 packages, $13,051; 3 cases automobiles, $500; London, 53 packages, $11,676; 12 boxes, $850; Marseilles, 29 packages, $303; Mexico, 93 packages, $9,221; 1 case, $139; 4 cases automobiles, $5,583; Naples, 25 cases, $500; Newfoundland, 31 packages, $545; Newcastle, 17 packages motor machinery, $4,100; Nova Scotia, 22 packages, $304; Peru, 1 package, $5; Porto Rico, 226 packages, $672; Rostoff, 22 cases, $3,531; Southampton, 3 packages, $217; U. S. Colombia, 13 cases, $223; Venezuela, 271 packages, $1,402; Vienna, 42 cases, $7,097.

PERSONAL MENTION.

Donald J. Hutton of Schenectady, N. Y., who has been for several years employed by the General Electric Company, left recently for the City of Mexico, where he will be connected with the General Electric Company's plant in that city.

Mr. James J. Lawton of New Haven, Conn., was recently elected a director of the Enfield and Long Meadow Street Railroad Company, to fill the vacancy made by the death of the late Israel A. Kelsey.

Mr. Charles E. Carpenter of Bronxville, N. Y., has resigned the vice-presidency of the Ward Leonard Electric Company and will shortly engage in the business of manufacturing electric flat irons.

Mr. J. W. Holloway of Syracuse, O., has been chosen manager of the new plant of the Economy Electric Company in Warren, O.

Mr. John K. Pruyn, who died at his home in this city last week, was interested in many investment projects, among which were the Union Railway Company, the Troy City Railroad Company, and the Gas & Electric Works of Troy, N. Y.

Mr. Samuel Glover, president of the Post-Glover Electrical Company of Cincinnati, O., was severely injured by a fall a short time ago, from which serious results are feared.

INCORPORATIONS.

The Electric Carriage & Transfer Company, San Francisco, Cal. Capital stock, $250,000. Incorporators: Charles Montgomery, W. H. Jordan, George H. Montgomery, B. F. Riker and L. H. Johnson.

The Forest City Incandescent Mantle Company, Cleveland, O. Capital stock, $10,000.

The Crocker-Wheeler Electric Company, New York City. Capital stock, $1,000,000. Incorporators: Frank M. Jeffery, William H. Geers, Gano S. Dunn, Henry H. Crocker and Augustus K. Sloan.

The Ripon, Dartford & Green Lake Traction & Light Company, Madison, Wis.—to operate an electric road between the points named and furnish light. Capital stock, $100,000. Incorporators: J. S. Roundtree, O. Schallum and H. P Cody.

The Missouri River Power Company, Jersey City, N. J.—to manufacture electricity, etc. Capital stock, $2,000,000. Incorporators: Samuel T. Hauser, Barton Sewell and Henry Suhr.

The Hughes Light & Heating Company, Pittsburg, Pa—to deal in gas and electrical appliances. Capital stock, $100,000. Incorporators: W. G. Hughes, J. O. Kiskaddow, G. W. Gilmore, J. Armstrong, all of Pittsburg, and J. P. Appleman of Allegheny.

The Canadian Churchmont Motor Company, Wilmington, Del. Capital stock, $500,000.

The Ithaca Electric Company, Ithaca, N. Y.—to manufacture electricity for light, heat and power. Capital stock, $50,000. Directors: Herman Bergholtz, D. M. Dean, Ithaca, and W. K. Turner, Philadelphia.

The American Institute of Electro-Therapeutics, New York City. Capital stock, $5,000. Directors: S. G. Tracy, W. H. McIntosh and E. E. Black, New York City.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 23, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

660,487. Electric Brake. Frank E. Case, Schenectady, N Y., assignor to the General Electric Company of New York. Filed Aug. 5, 1898.

660,502. System of Motor Control. Alexander S. Garfield, Paris, France, assignor to the General Electric Company of New York. Filed March 11, 1899.

ELECTRIC LIGHTS AND APPLIANCES.

660,154. Receptacle for Incandescent Lamps. Philip H. Fielding, New York City. Filed April 2, 1900.

660,271. Insulating Knob for Electric-Light Wiring. Robert H. Henderson and John G. Henderson, Chicago, Ill. Filed Dec. 10, 1897.

660,393. Electric-Arc Lamp. John J. Rathbone, London, Eng., assignor of two-thirds to Eric Rivers Smith and Charles Bean King, Jr., same place. Filed Feb. 24, 1900.

660,475. Manufacture of Incandescing Electric Lamps. William L. Voelker, London, Eng., assignor to Theron Clark Crawford, New York City. Filed Nov. 20, 1899.

ELECTRICAL MACHINERY AND APPARATUS.

660,217. Electric-Motor Wheel. Charles E. Isbills, Passaic, N. J. Filed Dec. 13, 1899.

660,263. Electric Linotype-Machine. Alfred W. Storm, Ramsey, N. J. Filed Sept. 22, 1897.

660,459. Slot-Wedge for Dynamo-Electric Machines. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 21, 1900.

660,534. Regulating Dynamo-Electric Machines. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 18, 1899.

660,539. Coin-Controlled Electric-Shock Machine. Bethuel M. Davis, Chicago Ill., assignor to the Advance Machine Company, same place. Filed Feb. 12, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

660,124. Telephone System. Lambert Schmidt, Weehawken, N. J. Filed March 8, 1900.

MISCELLANEOUS.

660,113. Panel-Board and Fuse Holder. Charles J. Klein, New York City, assignor to the General Incandescent Arc Light Company, same place. Filed March 14, 1900.

660,134. Automatic Circuit Breaker and Closer. William B. Watzel and Forest L. Shekell, Washington, D. C. Filed Jan. 4, 1900.

660,138-660,139. Thermo-Electric Cell. Ernest F. Yost and William H. Smith, New York City. Filed June 28, 1900.

660,140. Insulator. Cassius Alley, Pendleton, Ind., assignor of one-third to Charles Henry Miller and Henry Wagner, Anderson, Ind. Filed April 9, 1900.

660,152. Electric Welding Tongs. John R. Duncan, Indianapolis, Ind., assignor of five-eighths to Calvin F. Darnell and C. Augustus Schmidt, same place. Filed May 17, 1900.

660,155. Apparatus for Controlling Mechanism of Moving Vessels or Vehicles. Bradley A. Fiske, U. S. Navy, assignor to the Western Electric Company, Chicago, Ill, Filed Sept. 7, 1898.

660,156. Method of Controlling Moving Vessels or Vehicles. Bradley A. Fiske, U. S. Navy, assignor to the Western Electric Company, Chicago, Ill. Original application filed Sept. 7, 1898. Divided and this application filed April 2, 1900.

660,199. Telautograph or Facsimile-Telegraph. Anton Pollak, Szentes, Austria-Hungary, assignor of one-half to Friedrich Silberstein, Vienna, Austria-Hungary. Filed May 25, 1898.

660,228. Plate or Element for Storage Batteries. Elmer A. Sperry, Cleveland, O. Filed March 24, 1900.

660,275. Phonograph Sound-Box. Frederick Myers, New York City, assignor, by direct and mesne assignments, to the Stylo-phone Company, same place. Filed March 22, 1900.

660,293. Electric Meter. Thomas A. Edison, Llewellyn Park, N. J. Filed Sept. 16, 1899.

660,305. Thermo-Electric Battery. Jesse Oliver, Memphis, Tenn., assignor to Thomas B. Turley and West J. Crawford, trustees, same place. Filed Feb. 8, 1900.

660,320. System of Electrical Distribution. Charles I. Young, Philadelphia, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed March 6, 1900.

660,340. Safety Cut-Out for Electric Circuits. Joseph Sachs, Hartford, Conn. Filed July 10, 1899.

660,352. Electric Temperature-Indicator. Leslie S. Wilder, Springfield, Mass. Filed Feb. 17, 1900.

660,375. Electric Battery. Frank K. Irving, Newark, N. J., assignor of one-half to Andrew G. Vogt, same place. Filed March 19, 1900.

660,385. Self-Winding Electric Clock. Augustine J. Madden, Prahran, Victoria. Filed Dec. 23, 1899.

660,396. Electric Regulator. Charles W. Richards, Needham, Mass., assignor of one-half to Winthrop M. Chapman, same place. Filed Aug. 21, 1899.

660,416. Manufacture of Reflectors. Sherard O. Cowper-Coles, London, Eng., assignor of one-half to the Reflector Syndicate, Limited, same place. Filed Nov. 7, 1898.

660,469. Signaling System. Edward J. Silkman, Baltimore, Md., assignor of one-third to Charles Selden and Edgar Wesley Day, same place. Filed March 25, 1898. Renewed Aug. 6, 1900.

660,483. Transmission of Power. Ernst J. Berg, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 16, 1899.

REISSUE.

11,865. Method of Insulating Electric Conductors. Nikola Tesla, New York City. Filed Sept. 21, 1900. Original No. 655,838, dated Aug. 14, 1900.

DESIGN.

33,430. Electric-Arc-Lamp Casing. Edward H. Belden, Fort Wayne, Ind. Filed Aug. 13, 1900. Term of patent 14 years.

The Electrical Construction Company of London, Ont., Limited, is asking for tenders for the erection of a new factory. It is the intention to have a three-story building 40 by 100 feet. The Electrical Construction Company from a small concern has risen to great proportions. This will be another addition to the manufacturing interests of that city, as the increase in its business will without doubt demand more help.

THE TELEPHONE WORLD.

American Telephone & Telegraph Company.

There have been conferences in Boston of late between the American Telephone & Telegraph people and the presidents of the following companies:

James E. Caldwell, president Cumberland Telephone Company; George N. Stone, president Bell Telephone Company of Cincinnati; Chas. J. Glidden, president Erie Telephone system; John I. Sabin, president Pacific States Telephone Company; Chas. F. Sise, president Bell Telephone Company of Canada; George Y. Wallace, president Rocky Mountain Bell Telephone Company; Wm. A. Jackson, president Central Union Telephone Company.

The above represent companies operating over 300,000 telephone subscribers for fully 50 per cent. of the Bell system in the United States and all of the Canadian system.

Now that the American Telephone & Telegraph Company has moved to New York, there is every reason to believe that a practical New York telephone man will succeed to the presidency of the parent company, and Mr. Chas. F. Cutler, president of the New York Telephone Company and a director in several of the Bell subsidiary companies, is prominently mentioned in telephone circles for that office. Mr. Cutler has been connected with the telephone business for over twenty-two years, was formerly a resident of South Framingham, but has lived many years in New York and is considered by all telephone men as one of the ablest managers in the country.

The Chicago Telephone Company's reduction of rates, which has lately been announced, applies only to such limited conditions as to make no very material change in the previous basis. Some nickel-in-the slot telephones have been put in where there are ten 'phones to one wire, and under these circumstances a five cent rate is in force. This only applies to the residence districts and was intended to give a limited service at a cheap rate to a number of small subscribers. Not a single public pay station in the city has been put on the five-cent toll scale, and the company says that none will be. The ten-cent rate in force in this city is said by the telephone men in Chicago to be the lowest possible under existing conditions for cities of such large size. There are 75,000 telephones in the New York system. In Chicago there are only about 20,000.

It is learned that the American District Telegraph Company is considering the installation of a telephone service as an adjunct of its messenger business. It is experimenting with a telephonic device called the audiphone, now in use in Chicago. The audiphone, if adopted in New York, will be used for telephoning for messengers to be dispatched with oral messenges, it is said, but the American District Telegraphic call boxes would continue to be used for calling boys for carrying parcels and notes. This contemplated move of the American District Telegraph Company, it is said in Wall Street, is the basis for the rumor that the American Telephone & Telegraph Company is about to institute a messenger service.

The Sunset Telephone Company is going to rebuild the system between Redding and Weaverville, Cal., Keswick and Shasta, will also have separate lines. At present the two towns are on the Redding-Weaverville line. The business justifies a separate line for them and a loop will be strung. The poles now in use will be used, and the expense of the new modern line will not be very great. It will improve the service very much.

The Kansas City Telephone Manufacturing Company has lately closed a contract with Mr. S. F. Cunningham, representing the Norborne Telephone Company of Norborne, Mo., for a complete system for that city. A Eureka metallic express switchboard of 100 capacity will be used. The instruments are the Kansas City Telephone Manufacturing Company's best make and when finished this will be one of the finest and most modern exchanges in that State.

A special committee of citizens and aldermen of Jackson Mich., met with J. F. Land and W. E. Thompson, of Detroit, Mich., representatives of the Michigan Telephone Company, with reference to improving the local service. The telephone company wishes to put in a system of conduits which, it is claimed, is necessary for better service. A new switchboard is also promised. A special meting of the council has been called to consider a formal proposition of the telephone company.

A charter was issued last week to the Carbon County Telephone & Telegraph Company of Mauch Chunk, Pa., with a capital of $30,000.

The poles for the new telephone line to the "Shakers" are nearly all set up. This is part of the local line that runs to the station at East Gray and New Gloucester, Me.

Telephone Company Seeks Franchise in Chicago.

The United Telephone, Telegraph & Electric Company, an independent organization operating more or less in the Mississippi Valley, has applied to the city council of Chicago for a franchise to operate a telephone system in that city. The company has a franchise in Hyde Park, now a part of Chicago. This was obtained in 1898, when the Hyde Park District Telephone Company was formed to provide a telephone service in competition with the Bell. That company's franchise was bought by the United Telephone, Telegraph & Electric Company in 1894.

The company now announces its intention to lay its conduits downtown in the business quarter of the city, and will charge $85 for a business telephone, and $50 for a house telephone for unlimited service.

In return for the franchise it will pay the city 3 per cent. of its gross earnings, the first five years, 5 per cent. the next ten years, and 7 per cent. the next ten years. It also agrees to have 2,000 telephones within the first ten years or forfeit its plant and franchise. These propositions are embodied in the ordinance presented to the city council.

The new move on the part of the United Telephone, Telegraph & Electric Company is said to be due to the recent change in the ownership of the company. About a month ago Willard T. Black acquired a large block of the stock and was elected president to represent the new interest. The company claims to have 500 subscribers, but they are confined to the Hyde Park district. There is not much chance for expansion in that district, and unless a franchise is granted the plans for a long distance service between Hammond, Ind., and Chicago will be abandoned.

A recent meeting of telephone men in Marion, Ind., discussed the proposed consolidation of the various independent telephone companies north of Indianapolis. It is said an offer was made for the local plant, and, if bought, $18,000 will be spent to improve it. Among those present were Hugh Daugherty, L. C. Davenport, F. C. Oppenheimer and James B. Sale, Bluffton; John W. Sale, Ft. Wayne; H. L. Sale, Indianapolis. The Bluffton parties and John W. Sale represented the United Telephone Company, which controls the independent systems of Huntington, Portland and Bluffton, Ind.

The people of Dauphin County, says the Harrisburg, Pa., "Independent," are charged enormous tolls by the Bell Telephone monopoly for messages sent from one point in the county to another. The Court House ring have prevented a free county service to users of telephones by "persuading" select council to defeat the independent telephone ordinance. This is another instance in which the people of Dauphin County lose enormously by keeping the ring in power.

The directors of the Tidewater Telephone Company met at Gloucester C. H., Va., a short time ago. W. W. Fields, assistant superintendent, was elected manager of the Saluda exchange, which will be open soon with about forty 'phones. The issue of five hundred dollars' worth of additional stock was authorized to cover the increased cost of the Tappahannock, Va., line.

The decision of the Supreme Court, deciding section 3,461, Revised Statutes, unconstitutional, will stop contemplated proceedings in Millersburg, O., by telephone companies to get a franchise through the Probate Court, having failed to get it from the council, and they will now make another effort in the council to get into town.

The Iowa Telephone Company is said to have almost closed a deal whereby it becomes the owner of the Central system which has lines as far northeast as Baxter and also to Ames. The lines of this system go also to Newton and Oskaloosa. The Central has been one of the independent systems entering Des Moines.

A stock company has recently been formed in Tyndall, S. D., for the purpose of putting in a local telephone exchange. It will be in working order very soon.

A telephone line will soon be built from Mountain City to Shady, Tenn., a distance of twelve miles. When this line is completed the entire county will be very well connected.

The Blue Earth Telephone Company of Blue Earth City, Minn., is at present, with a large force, remodeling its entire plant and wiring in that city, at an expense of about $3,000.

The contract has been let for the building of the proposed telephone exchange in Villa Rica, Ga.

Independent 'Phones for Greeley, Col.

The Greeley Independent Telephone Company is now assured. The Bell telephone will have competition throughout Colorado, if the plans of the Independent Company are carried out.

Not long ago the city council of Greeley granted the Independent Company a franchise to erect poles, string wires and conduct an exchange. This was done in the face of strong opposition on the part of the Bell Company.

The people of Weld County have felt the need of a new telephone system for a long time, and when the local company was formed expected that it would be supported by the entire community, but strong opposition arose, and six months' delay ensued before the right to put in an exchange was granted.

It is proposed to put telephone exchanges in all the towns in the vicinity of Greeley, and then to extend the system over the State as rapidly as possible. It is believed by the promoters that the growth will be phenomenal, as the company is backed with abundant capital, and has means of obtaining the most improved appliances, and does not demand so high a rate of interest on money invested, and carries no watered stock for patrons to pay dividends on. The rate charged for telephones is to be about one half that demanded by the Bell Company.

Independent companies have been established all over the United States during the past five years, and in nearly every instance have proven beneficial to the public. The service has invariably been bettered, as the lowering of prices has resulted in the use af a much larger number of 'phones.

The Clay Telephone Company has held a conference with its attorneys, James Gay Gordon and George S. Graham and decided to sue the city of Philadelphia and the Keystone Telephone Company, charging that a franchise granted them by councils was illegally revoked. The amount of damage to be asked is nearly $1,000,000, it is reported. This claim is made on the ground that the city has had the use for the past decade of 300 miles of poles and wires, which the Clay Company erected and never used for its own profit. When the company first put up the wires and poles an injunction was issued against it by the Bell Telephone Company, and it was forced to let them stand idle until the patents of the Bell Company expired. Then a franchise was secured from councils and shortly afterward repealed, when the Keystone deal was made.

A. H. Springer of the Pacific States Telephone Company has commenced the construction of a branch line from Stevenson, Wash., to connect with the line on the Oregon side. The line will run from Stevenson to the Cascades, where it will cross the Columbia River. Stevenson has hitherto been without telegraph or telephone communication.

The Pacific States Telephone Company has completed a heavy copper loop between Portland and Astoria, Ore., also another between Portland and Tillamook, Ore., which enables both of these places to talk satisfactorily to San Francisco and other distant points.

It is stated that the Southwestern Telephone & Telegraph Company will make no charge for local exchange service in Galveston, Tex., until December 1 to subscribers who will agree to continue service for a period of six months from that date.

The Massachusetts Telephone & Telegraph Company, says the Boston "Post," expects to be operating its first switchboard December 15 with 1,800 connected subscribers.

A trench has lately been dug along the north side of the Boulevard in Arverne, N. Y., to receive the conduit for the wires of the New York & New Jersey Telephone Company.

The Gainesboro Telephone Company of Crossville, Tenn., is putting up a copper wire to Rockwood and also putting in a number of local telephones along the line.

Early next spring the Vernon & Nelson Telephone Company will build a direct telephone line from Rossland, B. C., to Cascade.

TELEPHONE INCORPORATIONS.

The Extension Telephone Company, Conejos, Col.—to erect or purchase telephone lines in Conejos County. Capital stock, $5,000. Incorporators: Jose A. Garcia, H. H. Russell and F. Warshaur.

The Queen City Telephone Company, St. Louis, Mo.—to construct and operate telephone lines. Capital stock, $50,000. Incorporators: C. G. Chaddock, F. A. Churchill, H. M. Dix, G. R. Henderson, all of St. Louis; G. Chaddock, of Los Angeles.

GENERAL ELECTRICAL NEWS.

Lighting.

Bakersfield, Cal.—An electric lighting plant will soon be erected by the West Shore Company.

Burton, Wash.—An electric light plant will be erected here for Vashon College. Address President Jones.

Columbia, B. C.—This city is preparing to establish an electric light plant. J. A. McCallum, city clerk.

Eagle's Mere, Pa.—A party of capitalists including H. Lausatt Geyelin, of Philadelphia; C. Larus Munson, J. R. T. Ryan and William Emery, of Williamsport, are interested in a project to establish electric light and water plants here.

Gurdon, Ark.—The Gurdon Mill & Gin Company recently incorporated with $5,000 capital stock, of which E. A. Whitman is president, will in the near future erect an electric light plant.

Hartford, Mich.—This place is to have electric lights for the streets.

Hammondsport, N. Y.—Arrangements are being made to light many of the business places here with electricity.

Ithaca, N. Y.—H. Bergholtz has applied to the city council for a franchise to erect an electric light plant.

Kasson, Minn.—Plans are being prepared for a $5,000 electric light plant here to replace the one destroyed by fire some weeks ago.

Kirkwood, Mo.—At a recent meeting of the board of aldermen the St. Louis Electrical Supply Company was awarded the contract for furnishing the municipal electric lighting plant for this place.

Laurel, La.—At a meeting of the mayor and board of aldermen, held recently, F. W. Pettibone was authorized and granted the right of the streets and sidewalks for constructing and operating an electric light and power plant.

Lewiston, Pa.—The council will receive bids until November 5 for lighting the streets with 30 or more arc lights of 2,000 candle power.

Mantorville, Minn.—C. S. Wedge & Sons, owners of the Mantorville Roller Mills, will install an electric light plant to light this city.

Middleport, N. Y.—The question of erecting an electric lighting plant, to be owned and controlled by this village, is agitating the municipality at present. A committee, consisting of C. H. Cramer, chairman, has been appointed to visit villages owning their own plants, and ascertain the advisability of recommending to the taxpayers a like ownership.

Middletown, N. Y.—W. J. Hinchey is interested in the electric light question that is being agitated here.

Newman Grove, Neb.—The citizens of this place are agitating the question of erecting an electric light plant.

Northport, N. Y.—The Northport Electric Light Company has contracted to furnish lights to the Carmandale stock farm, on the road from Centerport to Huntington.

Norwich, N. Y.—E. F. Murray of Troy and L. W. Emerson of Warrensburg, owners of the Norwich electric light and gas plants, have decided upon some necessary improvements in their property.

Petersburg, Va.—A stock company will doubtless soon be organized here for the purpose of establishing a new electric light plant. It is believed that the demand for a first-class electric light plant fully justifies the prospective enterprise.

Richmond, Tex.—There is some talk of the electric light plant being placed in running order in the near future.

Ripon, Wis.—Bids are asked until January 3 for privileges and franchises for supplying electric light for this city. Propositions may be for five, ten or fifteen years. Address F. W. Allen, city clerk.

Spokane, Wash—The Washington Water Power Company has made another reduction in the cost of electric lighting. The change will go into effect on all bills rendered after November 1.

Wilton, N. D.—Wilton will soon be lighted by electricity from a plant located at the new coal mine owned by W. D. Washburn.

Windsor, Conn.—The prospects of having an electric lighting system here are now quite promising.

Street Railways.

Albany, N. Y.—The owners of the Albany Street Railway system contemplate putting in an electric line in place of the steam power now in use.

Battle Creek, Mich.—The post office department has awarded a contract to the Battle Creek-Kalamazoo Electric Road to carry mail on Sundays between the two cities for villages on the line.

Delaware City, Del.—It is rumored that a trolley road is to be built from here to Augustine Park, crossing the canai over an iron bridge to be built.

Elkton, Md.—Messrs. P. M. O'Brien, T. F. Deegan and Capt. Higgins, capitalists, have subscribed to the whole of the capital stock of the Cherry Hill, Elkton & Chesapeake City Electric Railway, and construction of the road will begin soon.

Fairmont, W. Va.—The stockholders of the Fairmont & Clarksburg Electric Railway met last week and elected the following directors: J. N. Camden, S. D. Camden and I. Davis, of Parkersburg, and others. The purpose of the company is to build an electric passenger railroad from Clarksburg to this city, through the Camden coal fields.

Grass Lake, Mich.—W. A. Boland has secured franchises for his electric road from the authorities of both Dexter and Ann Arbor. Mr. Boland will extend his road from the latter city to Detroit via Plymouth. Work has commenced on the line between this place and Jackson.

Lancaster, Pa.—The building of an electric railway from this city to Manheim is contemplated by local capitalists.

Lima, O.—The Western Ohio Electric Railway Company has been incorporated with $1,000,000 capital stock. The company will soon begin to build a line from this city to Wapakoneta and St. Marys.

Marietta, O.—Col. E. A. Boone is here securing the right of way for an electric railway from Zanesville and Parkersburg.

Media, Pa.—An electric line from here to Geneva, O., is projected. The distance is 48 miles.

Middletown, Conn.—There is again strong talk of equipping the Middletown, Meriden & Waterbury road with the third rail electric system.

Newport News, Va.—The city council lately granted a franchise to the Hampton Roads Railway & Electric Company to operate a street railway within the city limits. This railway company proposes to build a road from here through Hampton to Old Point.

Oklahoma, Okla.—A charter was lately issued for the Sulphur Springs Electric Railway Company with headquarters in this city and branch offices at South McAlester and other points. The road will cost $250,000 and will be 24 miles long.

Parkersburg, W. Va.—A company has been formed to build a trolley line from here to Marietta, O. The road will be constructed within a year and will make tributary to Parkersburg all the towns about the city for 12 miles. H. C. Henderson is president of the pany.

Pontiac, Mich.—A company of Eastern capitalists has been organized to take control of the Pontiac-Flint Electric Railway. The plan is to build a double track line from Detroit to Bay City.

Selma, Ala.—It is thought that by February 1 the electric car system will be completed.

South Haven, Mich.—John J. Sturm of Chicago has presented a petition to the council of this city asking for a franchise to build an electric railroad from here to Paw Paw Lake.

Company Matters.

Millbury, Mass.—The Millbury Electric Company lately elected these officers: Treasurer, Herbert A. Ryan; clerk, J. H. Searles; directors: Thomas Robinson of Dedham, George Smith, of Boston, P. W. Wood and J. H. Searles, of Worcester, and Herbert Ryan, of this city.

Reading, Pa.—The Metropolitan Electric Company is about to sink an artesian well. The object is for emergency purposes, so that in the event of an accident to the city supply the company will have another source to fall back on.

Sharon, Pa.—Representatives of the New York Trust Company purchased the Shenango Valley Electric Light plant here October 25, and also the Sharpsville Electric Light Works. The company will build electric railroads connecting Sharon, New Castle and Youngstown, and will invest over $2,000,000 in the towns above mentioned.

Manufacturing.

Dover, Del.—A recently incorporated concern, known as the National Pianist Corporation, has been formed here for the purpose of manufacturing mechanical piano players by air or electricity with a capital stock of $250,000.

Hamilton, Ont.—The management of the Ontario Lantern Company has closed a deal with the Shelby Electric Company of Shelby, O., for the exclusive rights to manufacture and sell the Shelby incandescent electric lamp in Canada and for export.

Washington, Pa.—The instruments for the electrical clock system, invented by A. French Poole of this place, are to be manufactured on a large scale at Wheeling.

Power and Transmission.

Cornwall, Ont.—The Shieks Island dam, at the foot of the Longue Sault Rapids, ten miles west of here, is to be used for electrical generation, which will transform the hitherto wasted energy into power that will light the Cornwall Canal and drive a good deal of the machinery in Cornwall that is now operated by steam

Haverstraw, N. Y.—The Buttermilk Falls Electric Company, with which Hon. W. C. Anthony of this city is associated, has purchased the Fort Montgomery mill property, which includes the entire water rights of the Popolopens Creek, supplied by Popole, Cranberry and Long Ponds. A new plant will be constructed, which will include a dam for storing water, a 150 horse power boiler and engine, and a new 2,000 volt alternating current dynamo of the latest type, made by the Stanley Electric Company.

Hot Springs, Ark.—James P. Turner of Chicago, has lately been here conferring with local capitalists regarding the establishment of an electric power plant on the Ouachita River, eight miles from this city.

Sacramento, Cal.—The Central California Electric Company, which has one of the largest power houses in the State, from which light and power is transmitted from Newcastle to this city, has decided to increase the capacity of its plant.

Automobiles.

Hartford, Conn.—The machinery in the factory of the Worcester Cycle Company will be turned over with the buildings by the American Surety Company to the New York Motor Vehicle Company. The machinery will be valuable in the manufacture of automobiles which will be commenced here shortly; the factory is already partly equipped.

Minneapolis, Minn.—The Blood-Mille Motor Vehicle Company has been formed here with a capital of $500,000. The concern will manufacture and deal in automobiles. Joseph W. Blood, Otto E. Mille and Bernard Tuchman, are all interested in the firm.

New Albany, Ind.—The Louisville Automobile Cab Company has been organized here lately, with a capital stock of $25 000. Among those interested are Peter Arund, James A. Windsor, Jr., William H. Sturvant, Clarence Dallam and George H. Hester.

San Francisco, Cal.—The California Automobile Company was recently incorporated here by Henry C. Whittemore, Michael J. Kirwin, Charles E. Hancock, Sherwood Bird and Norton C. Hulse, with a capital of $150,000.

St. Louis, Mo.—C. R. Drummond, C S. Scott and W. D. Pittman are interested in a newly-formed concern known as the Scott Automobile Company of this city, capitalized at $30,000.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Lake quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

Directors of the Westinghouse Electric Company have declared the regular quarterly dividend of 1½ per cent. on the assenting stock.

A dividend of 3 per cent. on Consolidated Traction of Pittsburg preferred stock has been declared, payable November 15, to holders of record November 6.

The directors of the Lowell Electric Light Corporation have declared a dividend of 2½ per cent., payable November 1 to stock of record October 24. Transfer books closed October 24 and reopen November 1.

Directors of the New England Telephone and Telegraph Company have declared a regular quarterly dividend of $1.50 payable November 15 to stock of record October 31. Transfer books close November 1 to November 14 inclusive.

The demand for the stock of the Electric Company of America in the Philadelphia stock market is brisk. It is believed that the regular rate of dividend is to be declared at the coming meeting. Earnings are said to be on the increase.

A special from Philadelphia says: "The Southern Traction Company of Pittsburg has been purchased by the Magee-Widener-Elkins interests of the Consolidated Traction Company. This is regarded as a step in the Union Traction consolidation plan."

The New York State Railroad Commissioners have permitted the Niagara Falls Street Railway to cross the New York Central tracks at grade, and have approved the issue of $750,000 first mortgage bonds by the Peekskill Lighting and Railroad Company.

We understand that Philadelphia Electric Company's earnings for the year ending next month, should show a surplus of something over $100,000 beyond the interest on the P. E. G. 5s. This is over 4 per cent. on the present amount paid in on the stock, $2.50, and on the basis of interest charges as they will stand next year these earnings would represent 8 per cent. on the stock, says the Philadelphia "Stockholder."

The Staten Island Electric Railroad reports for the quarter ending June 30: Gross earnings $78,255, increase, $5,342; operating expenses; $46,155, increase, $3,331; net earnings $32,100, increase, $2,011; other income, $177; increase, $2; total income, $32,277; increase, $2,013; fixed charges, $27,348; increase, $1,248; net income, $4,929; increase, $1,765.

The balance sheet of the Brooklyn City Railroad Company as of September 30, 1900, shows: Assets—Cost of road, etc., $18,925,000; other permanent investments, $350,894; open accounts, $2,787; cash on hand, $2,053; total, $19,325,743. Liabilities—Capital, $12,000,000; funded debt, $6,925,000; open accounts, $36,134; profit and loss surplus, $359,609; total, $19,325,743.

The Worcester (Mass.) Electric Light Company has filed the following certificate of its condition September 12 with the Secretary of the Commonwealth: Assets—Land and water power, $23,655; buildings, $56,920; machinery, $193,251; cash and debts receivable, $99,442; manufactures, merchandise, material and stock in process, $8,525; miscellaneous, $183,846; total, $565,639. Liabilities—Capital stock, $300,000; debts, $31,964; balance, profit and loss, $133,675; total, $565,639.

Advices from Pittsburg, Pa., state that bonds amounting to $3,000,000 belonging to the Southern Traction Company, the Widener-Elkins syndicate, were sold at the Farmers' National Bank in 75 minutes on October 25. Bids for $1,000,000 more were turned away. Pittsburg bought the whole issue, which are 50-year 5 per cent. gold bonds. They sold for $1,000 each. The capitalization of the company is: First mortgage, bonds, $4,000,000; preferred stock, $2,500,000; common stock, $2,500,000. Total, $9,000,000.

The American District Telegraph Company has declared a dividend of 1¼ per cent., payable November 15. Officials of the American District Telegraph Company say that the declaration of a semi-annual dividend of 1¼ per cent. is not an increase in the dividend, but is in accordance with the policy of the company to pay no more than it earns. The company earns more money in the last six months of the year than in the first six months, and last year and this year it declared 1 per cent. on the stock for the first six months and 1¼ per cent. for the last six months, making the annual dividend 2¼ per cent.

There are many rumors current regarding the Brooklyn Rapid Transit Company. Some are to the effect that President Rossiter is about to retire and that the control of the Company will pass to the Metropolitan Street Railway Company of New York or the Pennsylvania Railroad Company. That something is on foot there would seem little doubt, but just what will develop it is impossible to state authoritatively. Regarding the stock of this property the Boston "News Bureau" says: There has been some buying recently on expected good results from the quarterly statement to be filed next month. This will be for the quarter ended September 30, and it is known that the showing will be very favorable. It would not be surprising if Brooklyn Rapid Transit in the September quarter earned about as much on the stock as was earned in the whole of last year.

The annual meeting of the Massachusetts Electric companies is called for November 7 at 12 M., at the office of the trustees, 14 Kilby street, Boston, to elect five trustees, to change declaration of trust making annual meeting third Wednesday in November, instead of first Monday in November, and to authorize trustees to sell or otherwise dispose of certain shares of stock held by trustees. The notice to stockholders states that it will be "impossible to get the full figures of operations of the system in time to prepare the annual report to mail with this notice." The report will be ready about November 10 and will be mailed to each stockholder. No quorum therefore will be expected at the meeting on November 7 and no business will be proposed by trustees except to take an adjournment to 12 o'clock noon November 21, at Lorimer Hall, Tremont Temple, at which time the business above referred to will be taken up.

EDITORIAL NOTES.

"Electricity's" Educational Series.

We wish to call the attention of our readers to the fact that, beginning with the issue of November 14, we propose publishing in the columns of ELECTRICITY a series of articles of an educational nature on Electricity and its Practical Application. The aim of this series is to supply an immense demand arising from a great number of electricians and electrical workers for articles of practical benefit, written in an interesting and instructive manner, for we know that a vast majority of the young men who earn their living in electrical work have not had the good fortune to have a college course in electrical engineering and have learned what they know of the electrical science only by practical experience.

Our attention has been directed to the fact that a large number of the electrical articles published in the journals devoted to that science have been, with few exceptions, unsuited to the general class of the electrical workers owing to the too technical manner in which they were treated. This being the case the author proposes to treat this work in as clear and as popular a manner as the subject allows, making plain, problems that are puzzling to the average electrician, advancing his knowledge and increasing his efficiency in his business capacity. The essays will include such subjects as Electricity and Magnetism, Electrical Measurements, Laws of Induction, Dynamos, Motors, Alternating Currents, Primary Batteries, Storage Batteries, Simple Methods for Electrical Calculation, How to Test for Trouble, Hints for the Dynamo Tender, A Talk to Wiremen, The Telephone, The Telegraph, How to Install an Electric Light Plant, etc. This is only a partial list of the subjects. All will be written with a view of interesting and instructing, and will be illustrated by drawings and sketches so that they will be the more easily understood.

It is our intention to maintain the popularity of ELECTRICITY and to increase its usefulness so that it will be read by every electrical worker in the country. We also wish to add that no electrician can afford to be without it as its columns in this way will be devoted to the education and interest of practical men.

This work will be exclusive in this journal and will be written for us by R. Max Eaton of Philadelphia, a popular young electrician, and, in his own words, the articles will be "Just what you want to know and in just the way you want to know it."

* * *

Municipal Ownership of Street Railways.

The results obtained by the municipal ownership of street railways in England would seem to have tempted the city of Chicago to try, if possible, a similar experiment.

In the Windy City a Municipal Street Railway Commission has been appointed which proposes to introduce at the next session of the Illinois Legislature a measure conferring on the authorities of the city of Chicago the specific right to own and operate street railways. Under its provisions the city will be empowered to negotiate for the purchase of the present street railway plants within the city limits, or, as an alternative, to build an entirely new system.

In this country Detroit is about the only city that has gone in for municipal ownership of its street railways, although, if we are not mistaken, the Mayor of Toledo ran for office on a platform embodying the principle of municipal ownership of public functions.

The advocates of municipal ownership, when debating on the subject, invariably point with pride to the results obtained in Great Britain, and especially in Glasgow, where the fare averages about one cent. per half mile. Although this plan has proven satisfactory to the residents of the Scotch city, the same rate enforced by the street railway companies in New York or Chicago would bring about such a hue and cry as has not been heard for years. A person now rides in this city from the battery to his home in Harlem for five cents, whereas, were the Glasgow rates in force, it would probably cost him ten or twelve. Circumstances alter cases, and this saying applies as readily to the operation of street railways as

Digitized by Google

to anything else. Because municipal ownership of street railways has proved fairly satisfactory in such English cities as Liverpool, Sheffield, Leeds, etc., it by no means follows that municipal ownership would prove a thing to be desired in a city such as New York or Chicago. Moreover, in Great Britain the roads, though owned by the municipality, are generally leased to private companies to be operated under prescribed conditions, whereas we venture to say should municipal ownership of street railways become a common thing in this country, in the majority of cases the system, with its army of employees, would be indirectly controlled by whatever politician happened to be the leading spirit of the party in power. Under such circumstances an efficient street-car service is scarcely to be expected, and, owing to this unfortunate condition of affairs met with on all sides in this country, it is to be hoped the Illinois Legislature will make haste slowly in passing the bill the Chicago Municipal Street Railway Commission proposes to introduce.

* * *

The Telegraph System of Porto Rico.

At the next regular session of Congress, in all probability, the matter of the Porto Rico telegraph and telephone service will be taken up. At the close of the war with Spain the telegraph system in Porto Rico was in a most dilapidated condition, and it was only through the untiring efforts of the Army Signal Corps that communication was established between the most important points on the island. The operation and care of the existing lines are still in the charge of the Signal Corps, and it was with a view to making certain recommendations as to to their ultimate disposal that Brigadier-General A. W. Greely, Chief Signal Officer of the Army, recently issued a report addressed to Senator Foraker as chairman of the Committee on Pacific Islands and Porto Rico.

General Greely, in his report, gives a brief outline of the history of the installation and growth, or rather dry rot, of the telegraphic system under Spanish administration. It was not until 1872 that the construction of a telegraphic system was begun in Porto Rico and it was not until 1874 that San Juan was connected by telegraph with the seven departments of the island. This was just fourteen years after the first movement toward getting telegraph lines was begun. The first record of such a movement is in 1860, when the Spanish Government refused a proposition of Senor Don Manuel Cuevas to establish lines on the island. In the refusal Spain took the ground that the Spanish policy forbade the construction of telegraph lines, save under conditions which made Spain the owner of such lines, which, whenever constructed, should be administered and directed by the Government, whose property they were to remain. Spain then suggested that Government lines be built, and, after thinking of this subject for four years, the Superior Civil Government of Porto Rico asked Spain to authorize telegraph lines between San Juan and the chief towns of the seven departments. This authorization was given, but definite estimates were required. This requirement was in the year 1865 and the documents were duly forwarded to Spain. Then Spain sat on the proposition for a year and thought about it. Finally, on June 12, 1866, a royal order approved the estimate—with certain modifications. At last in November, 1866, six years after the project was first put in motion, the royal authority to build the lines was obtained. After fourteen years, in 1874, the little string of some 800 miles was at last completed and Porto Rico had a telegraphic service.

The service that was installed then was precisely the same service that the army found in operation there when the island was evacuated by the Spanish troops.

When the Spanish operators went out, because they were put out and because those who were left would not learn the American system, Signal Corps men were put in their places and are now operating the lines. This makes the work comparatively cheap in a way, for the Signal Corps men would have to be paid, no matter what they were put at; and yet because of the heavy losses during the cyclone and because of the small amount of commercial business on the island the lines have not paid expenses. In his report General Greely says:

"From a practical standpoint, however, if the military advantages of the lines are considered as offset by the pay, subsistence, etc., of the men of the Signal Corps, the normal receipts of these lines under military control will amount to about $12,000 annually, which probably will increase within a year or so to, say, $18,000 annually, an amount entirely adequate for the maintenance and operation of these lines by a paid civilian force."

General Greely refers to the ultimate disposition of the telegraph lines as follows:

"The future disposition of the telegraph lines of Porto Rico is one not free from difficulties. There are three courses open. First, the operation of these lines by the United States Post Office, as was done by Spain in the past; second, the transfer of these lines to the insular Government, with a view to their operation and maintenance at the expense of Porto Rico; third, their operation and maintenance, as at present, as military telegraph lines.

"The first plan would mean a large outlay annually of public money of the United States; and as it would involve a new department with an extensive personnel it has nothing in its favor except the idea that telegraphing is a Governmental function.

"The second plan involves a similar reorganization of the service with a civil staff and their transfer to the insular Government, which is coupled with a certainty that these lines would be a serious financial burden to the people of Porto Rico. There is only one class of Porto Ricans who could be benefited by gift of these lines to the insular Government, namely, the numerous telegraph personnel, which consisted at the time of the American occupation of not less than one hundred and eighty-four employes. It is evident, however, that the old personnel could not be re-employed except by abandoning absolutely American methods for Spanish methods, the latter including a foreign telegraph code and reading by register instead of by sound. Efforts to reinstate as civilian employes Porto Rico telegraph operators have very largely failed, owing to either the inability or unwillingness of such operators to learn American methods. The insular Government would be forced either to hire at high salaries American civilian operators or to return to former Spanish methods.

"The third plan seems to the Chief Signal Officer of the Army the easiest and most natural solution of the question. Porto Rico must necessarily be fortified and garrisoned by troops of the Regular Army, and as it is a detached island, liable in time of war to certain invasion, it is of the utmost military importance that the different garrisons should be in either telephonic or telegraphic communication, thus insuring the greatest possible military efficiency of the defending forces.

"If this suggestion is adopted it may be added that for the execution of this plan no legislation is necessary, as the Signal Corps of the Army is now charged with the operation and maintenance of these lines until action is had thereon by the Congress of the United States. The same policy would be followed with those military lines as elsewhere, namely, the gradual condemnation and sale of lines no longer necessary in the public interest and the maintenance of only those necessary for strictly military purposes."

From the foregoing it will be seen that no suggestion has been made that a private company take hold and operate the lines. As the telegraph system in Porto Rico will ultimately pay this might then be a good opportunity for some one of our large telegraph companies to step forward and make a proposition to the Government looking to the perfecting and operating of the system on that island.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The electrical tower at the Pan-American Exposition at Buffalo, N. Y., which is to be illuminated by electricity generated in Niagara Falls, has now reached a height of 210 feet and from its top one can obtain a view of Niagara Falls and all the surrounding country. As the framework progresses lighter beams are being used, and, as a consequence, the work will be much more rapid from now on. As the wood is built around the iron ornamental staff will be applied to it and some realization of the beauty of the Howard electrical tower, when finished, may be obtained.

G. F. Greenwood, chief engineer and general manager of the Havana Railroad Company, says that the company will begin running trolley cars in and around Havana on Feb. 1. It will have 100 cars, each with seating capacity for 32 passengers. There will be three power-houses, the engines of which are being completed in Milwaukee, Wis.

Mr. George Francis Sever, Pan-American superintendent of electrical exhibits, is authority for the interesting statement that the American Institute of Electrical Engineers has decided to hold its 1901 Convention in Buffalo, N. Y., in June. This Association includes in its membership all of the representative electrical engineers of the United States and Canada. The selection of Buffalo as its meeting place in the Exposition year will mean the assembling in that city of the brightest minds in that important branch of modern scientific research of which the two countries boast. Many of the great European experts will be there as well, for the Institute has sent out invitations requesting them to participate in the deliberations of its gathering next summer. Mr. Sever has been placed on the committee of entertainment, and on the committee which will have the arrangements of meetings and the papers to be read, etc.

A man from Ravenna, O., has invented a contrivance which he expects will revolution-

ize the working of the street-car trolley. The device is known as a trolley retainer and is attached to the ordinary trolley now in use. It is arranged so that it is impossible for the trolley to get loose.

THE Automobile Show in Madison Square Garden, which is being held under the auspices of the Automobile Club of America, was opened to the public on the evening of November 3. In all there are more than seventy exhibitors, showing about 300 styles of motor vehicles, with a total value of nearly $500,000. There are bicycles, tricycles, quadricycles, runabouts, stanhopes, victorias, landaus, surreys, cabriolets, coaches, cabs, omnibuses, delivery wagons, trucks, racing machines and some nondescripts. The biggest machine is a steam omnibus capable of carrying eighteen passengers. It has platforms at the front and rear, the same as those of a trolley car, and is a part of a large order from a corporation near by which will soon start a line of them. The bus weighs about three tons, and its boiler can develop twenty horse power. The smallest machine is a motor bicycle of 125 pounds having a gasolene motor of two and a quarter horsepower. These two vehicles represent respectively the most expensive and the cheapest machines in the show, as well as the heaviest and lightest; the bus is worth $4,000, the bicycle $280.

A PORT CHESTER band of forty pieces attracted attention at the recent political meetings in Westchester County, New York. Each musician carried a small electric light on his instrument. The current was furnished by a storage battery which the player carried in his pocket. The lights, which were of various colors, added brilliancy to the parades.

ELECTRICITY is to cut an important figure in the operation of the coal mines in the southern part of Fayette County in Pennsylvania. It will be used as a motive power inside on the chief haulage ways.

PROF. CARL MYERS of Ilion, N. Y., owner of the Frankfort Balloon Farm and Experiment Station, has been for the past four weeks at St. Louis under contract exhibiting his sky cycles, airships and ærial electrical torpedo. The latter is the most recent product of the Frankfort Balloon Farm, and its four weeks at the St. Louis Coliseum is its first appearance before the public. The professor stated that his electrical ærial torpedo is a hydrogen gas spindle of peculiar shape, adapted to avoid ærial resistance, balanced in mid-air and operated by the force of electricity driving the most powerful dynamo of its size ever constructed. There are two silken air planes on each side which catch the air. He said: "The purpose of the vessel is to demonstrate the ease with which real air navigation is accomplished and the ready means of accomplishing 'peace on earth' by dropping from the sky explosives so destructive as to annihilate the art of war." He will, it is said, give an exhibition at the Automobile Show in Madison Square Garden in this city.

IT is well for this country that a splendid exhibition of the products of the United States was made at the Paris Exposition, now soon to close. The Exposition will be a great benefit to the manufacturers on this side of the Atlantic. This is proved by the consular reports now being made to the State Department. They show an increased demand for electrical supplies and machinery from Europe. Orders are reported from countries and remote parts of the globe where imports with the American stamp have been unknown heretofore.

THE list of exhibitors at the Automobile Show to be held at Grand Central Palace November 14 to 24 (Horse Show period), suggests, at first glance, that it is a continuance of the Madison Square Garden Show, for a great number of the vehicle concerns already published as being in the Garden Show will exhibit at Grand Central Palace. Undoubtedly good business reason and common sense are back of the Palace exhibition as it occurs, not during the warmest political week of the whole campaign, but after the turmoils of election are over and when things have resumed their normal routine.

NEW YORK ELECTRICAL SOCIETY.

The New York Electrical Society held its first regular meeting of the season at the College of the City of New York on Tuesday, October 30, when in spite of the inclemency of the weather, a good attendance assembled to listen to various addresses on the electrical features of the Paris Exposition, and the work of the Electrical Congress. Mr. Carl Hering, President of the American Institute of Electrical Engineers, was the first speaker, and delivered an admirable address on the lighting features and novelties of the great show, making many cogent criticisms in passing on the features of merit or difference, in connection with the leading European and American exhibits. His remarks were followed by the exhibition of some very interesting and handsome lantern slides covering not only the technical features, but some of the more artistic and spectacular portions of the exhibition. He was followed by Dr. A. E. Kennelly, who addressed his remarks more particularly to the modern steam turbine, as illustrated by the "Turbinia," which was exhibited on the Seine, within the Exposition enclosure. He also took up and described in detail the mechanism of the moving sidewalk, his remarks being also accompanied by lantern slides. He took a very hopeful view of the future of the steam turbine, both ashore and afloat. The third speaker was Mr. C. O. Mailloux, who gave an entertaining description of the whole work of the Electrical Congress, and of the manner in which the American delegates succeeded in carrying through their programme with regard to the new units which were adopted, or rather approved officially. Mr. Mailloux's references to the manner in which the members of the Society had taken an active part in this work elicited very hearty applause. At the close of the meeting, as some little recognition of the courtesy of Messrs. Hering and Kennelly in coming before the Society and entertaining its members so instructively, they were elected honorary members by a hearty and unanimous vote of thanks. Following up the admirable work done during the two years of his administration by President Dunn, the Society has started out on its present season with renewed hope and vigor, and the secretary was able to present a list of twenty-seven candidates for membership, who were duly elected. It was also announced that during the present month Mr. Steinmetz will deliver a lecture before the Society on Alternating Current Work, and that in December, Dr. Sheldon will deliver an address on Electrical Measurements of Precision.

THE POLLAK-VIRAG WRITING TELEGRAPH.*

In the Pollak-Virag system of high-speed telegraphy [described in ELECTRICITY October 25, 1899] the receiver, it will be recalled, consisted of a telephone whose diaphragm was moved by impulses received from the line. To the diaphragm a rod was attached which moved one of three points on which a small concave mirror reposed; and the beam of light reflected from the mirror registered the movements of the telephone diaphragm on sensitized paper, which was moved forward uniformly on a drum. The small mirror was held in position on two pointed prongs of one pole of a stationary permanent magnet and one movable prong constituting the other pole of the magnet by having cemented on its back a small piece of

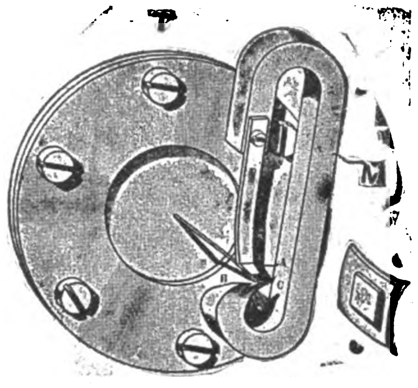

FIG. 1.

soft iron. It is to this movable prong that the rod from the telephone diaphragm was attached.

During the past year the inventors have greatly improved their apparatus. Fig. 1 shows the most recent type of diaphragm and mirror connection, while Fig. 2 gives a good idea of the arrangement of the parts of the complete receiving apparatus. By this apparatus messages are received and recorded in a zig-zag line as before; but now the record is traced in lines running from left to right of a broad strip of sensitized paper. This left-to-right movement is produced as follows: The source of light is a stationary glowing filament which is surrounded by the cylindrical metal mantle L (Fig. 2). In this mantle a helical slit is cut, the helix having one complete turn.

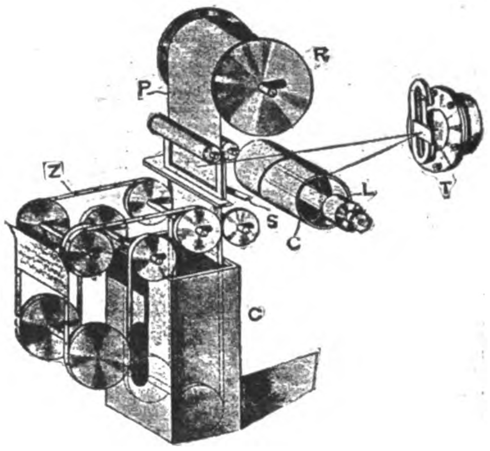

FIG. 2.

In consequence, when the mantle is appropriately turned about its axis, the source of the light falling on the mirror moves in effect uniformly from right to left, and hence the spot of light formed on the paper by reflection from the mirror moves uniformly from left to

* From the "Electrician," London.

Digitized by Google

right. A series of motions of the mirror about a horizontal axis is recorded, therefore, on the paper as an up-and-down zig-zag line running from left to right, and commencing at the left end of a new line on the completion of every filled one. On the commencement of a dispatch the revolution of the helically-slit mantle and of the sensitized paper feeder R is automatically started. At the close of the dispatch the paper strip is cut, and the movement of the unexposed paper stopped, while the exposed strip is carried forward by clockwork into the

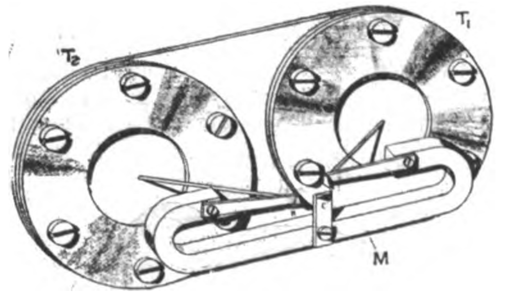

FIG. 3.

developing bath C, then into a neighboring fixing bath, and is finally pushed through a slot in the outer cover of the apparatus.

The apparatus in Fig. 1, however, yields only the zig-zag writing. For the recording of a message in the characters of ordinary handwriting, a double apparatus (Fig. 3) is necessary. This differs from the apparatus just described in having two telephones, and in having the concave mirror supported upon one fixed point and two movable points. One telephone moves the mirror about a horizontal axis the other about a vertical axis, so that acting simultaneously the telephones can cause the reflected spot of light to trace any desired curve. A double-line wire is used. One telephone is, as before, in the loop of this wire; the other is between the loop and the earth. For producing the horizontal motion a positive current and a negative current of approximately equal

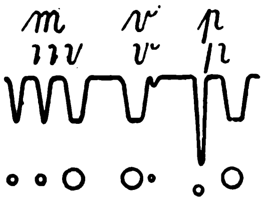

FIG. 4.

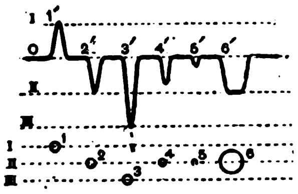

FIG. 5.

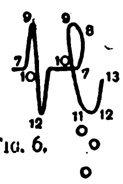

FIG. 6.

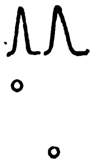

FIG. 7.

voltages are required; for the vertical movements a positive current and an equal negative current and a positive current of double their voltage serve. Corresponding to these are obtained motions to left and to right, and up-and-down motions of equal amplitude, and a downward motion of double this amplitude. Fractions of this amplitude are obtained by shortening the duration of the contact at the sending end. This contact apparatus consists of a perforated paper strip, five slip rings connected to the batteries, and two brushes connected to the line. The size of the holes in the paper determines the duration of the contacts between the brushes and rings.

If the ordinary written Latin characters be dissected it will be found that certain of them, such as *m*, *v*, *p*, can be resolved into elements each consisting of a down and up stroke commencing and ending at the same height above the line. The letter *m* consists, for example, of three such elements, the letters *v* and *p* each of two. In order to cause the receiver to write letters which can be analyzed in this way the currents sent from the sending end to produce vertical movements in the receiver are regulated with respect to direction, intensity and duration. This is done by perforating the paper strip with larger or smaller holes in three rows I, II, III (as in Fig. 5) corresponding to the three rings operated by one brush. A hole in row I, exposes to the brush the ring supplying a negative current of known voltage, in II the ring supplying a positive current of

PERFORATIONS.

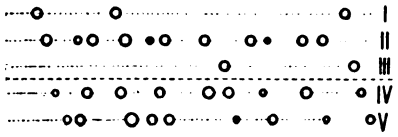

FIG. 8A.

VERTICAL.

FIG. 8B.

HORIZONTAL.

FIG. 8C.

RESULTANT

FIG. 8D.

equal voltage, in III the ring supplying a positive current at double that tension. And the effect on the mirror of the receiver of holes punched as in Fig. 5 is shown above the plan of the perforations in the same diagram. It is a matter of trial to fix on that size of hole which allows just sufficient time for the current to exercise its full effect on the telephone. A larger hole then merely broadens the loop the spot of light traces on the moving sensitized paper in the receiver; while a smaller hole displaces the spot of light to a distance which is a fraction of the full amplitude. The perforations necessary to produce the elements of the letters *m*, *v*, *p* are shown in Fig. 4, where the elements are, moreover, so combined and spaced as to write the letters distinctly and in order.

But the written Latin characters include many composed partly or wholly of closed curves, and these cannot be written by the mere up-and-down movements so far described: properly timed to-and-fro horizontal motions are necessary in addition. Such letters are therefore resolved into and compounded from vertical and horizontal components. The movements of the receiver mirror corresponding to each of these components are each produced by separate current impulses, and the time intervals between these impulses are chosen and obtained by deciding on the spaces to separate consecutive holes in the perforated tape. Take for example the letter *l*, which contains a closed curve or loop. Its vertical components merely, are written by the mirror as in the left-hand portion of the diagram in Fig. 6. This up-and-down zig-zag is the result of stimuli sent into the line through the perforations I, II, acting alone. The first hole, in row I, causes the curve 7, 9, 10, to be described on the moving paper; the second hole, in row II, produces the curve 10, 12, 13. But when a hole is, as shown in the figure, punched in the row IV, so that a current deflecting the spot of light from right to left is sent into the line, as soon as the spot of light in its upward motion due to hole I, reaches the place marked 8, a deviation to the left is produced—in spite of the forward march of the paper—which carries the spot of light to 9. Here the current through hole I ceases, and the spot of light returns to 10, where it is immediately, in consequence of the coming of hole II, given a downward motion towards 11. Here the effect of hole IV dies out, and the mirror, in restoring itself to its normal position, then writes on the moving paper the broad loop 11, 12, 13. Thus the second of the two telephones, by its production of horizontal to-and-fro motions of the mirror's normal, makes it possible to write letters containing closed curves.

In this manner any character of the alphabet can be written. The character must be analyzed at the sending end into its horizontal and vertical components defined as above and compounded at the receiving end by the two telephones. The telephone T_1, Fig. 2, gives the spot of light the vertical motions dictated by holes in rows I, II, III; the telephone T_2 the horizontal motions demanded by the holes in rows IV, V. The construction of the complete word "telegraf" on these principles is shown in Fig. 8. FIG. 8*a* gives a plan of the perforations in the sending strip; *b* gives the written record due to the telephone T_1 operated from the rows I, II, III; *c* represents the effect on the telephone T_2 of the holes in rows IV, V; and *d* is the resultant of the vertical and horizontal components.

The sources of current are two comparatively small batteries connected to the rings, line and

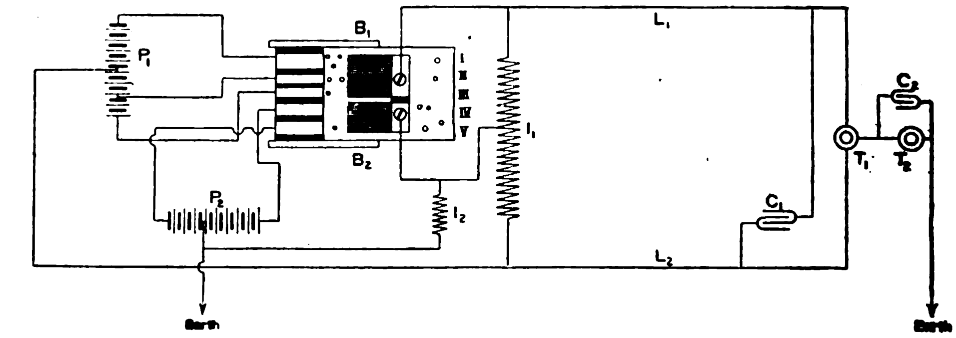

FIG. 9.

Digitized by Google

earth, as shown in Fig. 9. From the first battery P_1 are taken equal positive and negative currents corresponding to rows I and II of the perforated paper, and also a positive current of double the value corresponding to row III. From the second battery P_2 are taken a strong positive for the leftward deflection of the spot of light and a weak negative for the rightward deflection. It will be noticed from this diagram that, as before mentioned, only the telephone T_1 is included in the loop of the double line, the telephone T_2 receiving its impulses after they have passed as two oppositely-directed currents of equal strength through the telephone T_1.

The self-induction and the capacity of the wires and the effects of the natural oscillation-periods of the telephone diaphragms are compensated in a manner virtually identical with the method employed by Messrs. Pollak and Virag a year ago. These compensating coils and condensers are diagrammatically positioned in Fig. 9, where I_1 and I_2 are inductance coils and C_1 and C_2 are condensers. By modifying the condenser C_2, moreover, the phase difference between the horizontal and vertical motions can be adjusted to a certain extent. As a final detail we ought to add that the perforating of the paper sending-strip is accomplished by a simple machine which punches simultaneously all the holes corresponding to any required character.

There is in this system of telegraphy no need for the syntonizing of the sending and receiving apparatus, for variations in the speed at either end merely broaden or narrow the letters; and, therefore, the inventors claim that this system is simpler and more reliable considered merely from this point of view. Besides, with the aid of a distributer (such as Bandot's), about 30 sets of apparatus can work on one line.

At some recent trials, allowed by the Hungarian Minister of Commerce, a distance of 400 km. (nearly 230 miles) from Budapest to Pozsony and back was spanned by two pairs of telephone wires, and most excellent results were obtained. The rate of transmission—at which rate very good writing was produced—reached 1,000 words per minute through a resistance of 2,000 ohms.

AUSTRIAN ELECTRICAL EXHIBITS AT PARIS.

BY FRANK C. PERKINS.

A number of the Exposition buildings in the Esplanade des Invalides are lighted by current from the three-phase alternators of Ganz & Company of Budapest. A 1,200 kilowatt polyphase generator is operated by a cross-compound engine built by Erste Brunner Engine Company. This alternator has thirty poles mounted upon a revolving field which acts as a fly wheel for the engine. The speed of the engine is 125 revolutions per minute. The steam cylinders are about 20″ x 37″ in diameter, and the stroke is about 36″. This polyphase alternator generates a current having a frequency of 32 cycles per second and operates at a potential of 2,200 volts.

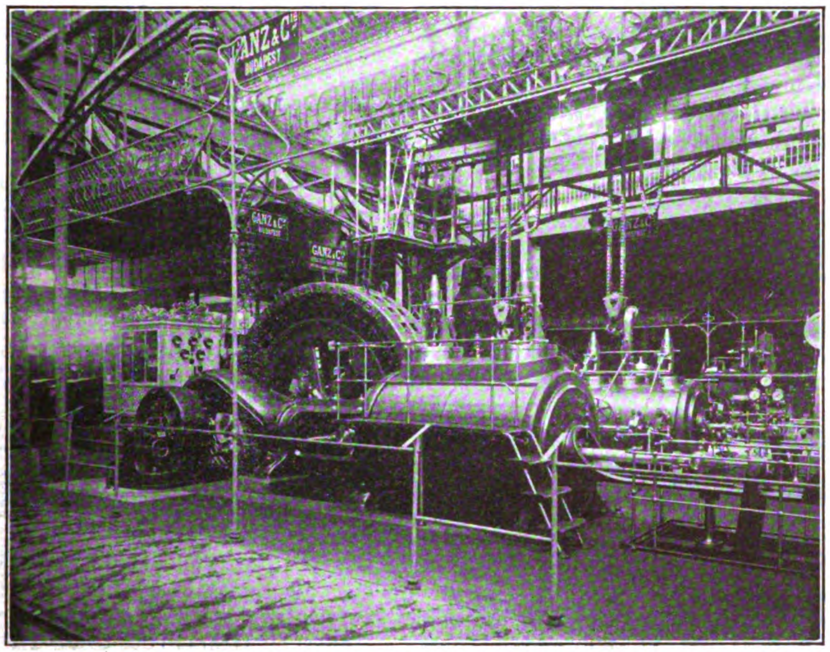

Fig. 1.—A Ganz & Co. 1,200 KW. Generator.

The current is conducted from this machine to the lighting circuit, after being transformed at five transformer stations located on the bank of the river below the Alma Bridge. The exciter for this machine is a multipolar direct current generator directly connected to the main shaft.

The historical exhibits of this company include transformers, motors and dynamos dating back to 1879. The "Transformateur a Manteau" was built in 1885. A polyphase generator is exhibited which was made in 1879 while a machine of the type "Gnom" was built in 1882. Among the other historical exhibits shown is a "Transformateur Noyau" dated 1880, and a machine of fair size marked "Moteur a Courant Alternatif Simple Continu, 1891."

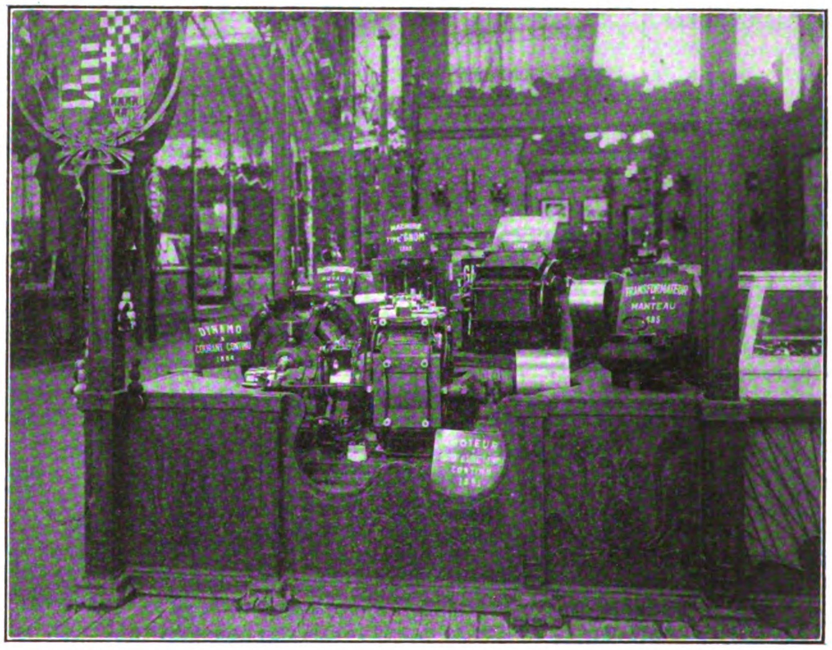

Fig. 2.—Historical Exhibit of Ganz & Co.

The alternator built by Ganz & Tarsa of Budapest, which is directly connected to the Lang cross-compound engine in the Austrian section, also furnishes a three-phase current at 2,200 volts potential, and has a frequency of 50 periods per second. This machine is located in the main exhibit of Ganz & Company, and in the same space is shown a new electric traveling crane, a smaller three-phase generator and exciter and a number of polyphase motors of various sizes and designs. A very fine line of arc lamps are shown in operation, together with some very interesting electrically-operated machine tools, including milling machines and stamping machines. The three-phase electric locomotive has received a great deal of study by this firm, and the locomotive exhibited has attracted considerable attention, as this field of work is entirely new, little having been practically and commercially accomplished in this line heretofore.

CONSOLIDATION OF STREET RAILWAYS AND ITS EFFECT UPON THE PUBLIC.*

BY DANIEL B. HOLMES.

It is no part of the purpose of this paper to enter into an extended discussion of street railway consolidations from a legal point of view. It is assumed that no considerable number of those present would be particularly interested in that branch of the subject. Suffice it to say that the laws of nearly, if not quite, all of the States of the Union are in such condition that practical street railway consolida-

* Paper read before the Nineteenth Annual Meeting of the American Street Railway Association held at Kansas City, Mo., October 16-19, 1900.

Digitized by Google

tion may be brought about and made effective by union of companies as a technical consolidation, or by purchase and sale of the corporate property or capital stock, or by common ownership of the corporate shares of several companies, or in other ways which might be mentioned. Whenever consolidation is desired by the parties in interest, it may be safely assumed that counsel learned in the law will find little or no difficulty in pointing out the way in which that end may be legally accomplished.

Street railway companies may be properly classified as public service corporations, and whenever a union takes place of several such companies, it at once becomes obvious that the interests of the capital invested and of the traveling public may and probably will be positively affected thereby. Therefore these two interests will form the chief basis of what I have thought proper to lay before this convention of practical street railway men, whose calling is such that they never feel at liberty to disregard either the best interests of their stockholders or the welfare of the dear public, whose constant servants they are. And I may be permitted to say, in the light of an experience and intimate association with street railway managers extending over a period of upwards of twenty years, that no class of men with whom I have come in contact in the active practice of a profession which brings about the most intimate relations with all sorts of men, are so constantly mindful of the best interests of the public they serve by night and by day as the street railway men. I am the more pleased to make this acknowledgement because the street railway man has so many impatient masters among the traveling public that he is much more often the subject of unjust criticism than of the well-deserved encomiums he would surely receive if the difficulties of his situation and his conscientious efforts to faithfully discharge his company's duty to the public were even half-way understood. Above all men it is his lot to bear the "whips and scorns of time," and if he will but pin his faith to the teachings of the Good Book, he may expect to receive hereafter that reward which in but few cases, I am sorry to say, comes in this life in the shape of an adequate salary for so hard and thankless a job.

That the consolidation of street railway interests affords opportunities for the introduction of many various economics is a truth which is almost axiomatic, and this may be fairly said to have been the controlling consideration which has inspired and accomplished the many consolidations which have taken place in various parts of the country. By this process the managerial force is greatly reduced and the salary list largely diminished. Where three or four presidents, managers or superintendents were required for the successful management of the separate properties, but one officer of each kind is needed in their united state, and while he receives more salary than any one of his predecessors, as of right he ought, because of enlarged duties and more weighty responsibilities, still there is substantial saving over what was previously paid.

But there is, in this connection, a still more important consideration. As is the case with any other calling in life, the supply of really first-class street railway managers is more or less limited, and the larger salary offered by the consolidated interests naturally commands, and in all probability secures, a higher order of talent than the separate properties could retain even where it had been fortunately possessed. In this way, the consolidated properties in nearly every instance are managed with greater ability than was shown by the management of the disconnected parts, and this is a positive gain, the value and importance of which can scarcely be estimated. This successful manager, you may be sure, is truly a remarkable man. The relations existing between street car companies on the one hand, and the municipality or its citizens on the other, are the fruitful source of jealousies and complications constantly arising which can be successfully disposed of by nothing short of the possession of genius for diplomacy, and for affairs and finance all at the same time, in order to be able to satisfy the demands of the public without involving the company in irretrievable financial ruin.

In most instances, the consolidation of street railway properties creates opportunities for marked reduction in the cost of generating motive power. Location is a most important consideration as regards the power station. Unless the power station is so situated that both fuel and water can be delivered to it at minimum cost, the highest degree of economy in developing motive power is altogether impossible. This is greatly facilitated by the union of properties since the car lines are so situated in most cities that but few of them, if independent, could operate from power stations located near steam railroad switches and water courses. A greater or less number of high priced employes are always necessary around every power station whether large or small, and this is an expense which is greatly curtailed by generating as much power as is practicable to handle from one station. A company possessed of an extensive system with large mileage has thus presented to it the opportunity of producing power at the minimum cost, a thing altogether impossible on a short line railroad.

But perhaps the most important result from consolidating street railway lines is the great stimulus it affords to street railway traffic. Outside of a few of the very large cities where the problem is not how to get business but how to successfully handle that business which of necessity must come to the car lines, the street railway companies are quite generally engaged in efforts of all kinds to create travel on the lines artificially by offering to the public attractions of various and sundry kinds. This is all well enough, but one of the most effective means to this end is the consolidation of the street car lines. I believe it is the uniform experience that the aggregate travel on the united lines exceeds by a large percentage the business formerly done by the separate properties. This is partially accounted for by the fact that short distances are now ridden which were formerly walked, because two fares were then necessary in order to ride, and this was considered too great an outlay for the accommodation afforded.

But how stands the case with the public? I am altogether sure it is no different. Indeed, the immediate benefit to those who ride upon the cars far exceeds the increased returns to the consolidated company. Where before the union, two and even three fares in some instances had to be paid in order to convey the passenger to his destination, he may now take the same journey for a single fare by means of transfers and through cars which were previously impossible. Taking Kansas City as an example 50 per cent. of all the passengers who ride on the cars make at least one transfer in every journey, so that it may be truly said that 60,000 passengers save five cents each and every day in the year in Kansas City alone, and this saving is due solely and directly to the consolidation which took place only a few years ago. And who are the people thus benefited? It is chiefly the laboring classes who can least afford to spend their hard-earned gains unnecessarily. The sons of toil who were formerly compelled to shelter their wives and rear their children in the polluted air and noise and smoke because unable to pay more than a single fare in going to and from their avocations, can, and do now, dwell in the neat little cottages in the suburbs where loved ones breathe the pure air of heaven and bask in the sunshine of life all day long, and when eventide comes, smiles and mirth and joy are the companions who have taken the place of sickness, suffering and grief. Who can estimate the value of blessings like these? If the public welfare is the first and highest duty of the State, who can gainsay the immense value to the public of street railway consolidations, and who can say that the State ought to throw any obstacles in their way.

But it is said that competition is the life of trade, and that monopolies are odious. Accepting these as general truths, let us see how it is with the street railroads. Except to a very limited and unimportant degree, there is no such thing as competition in street railroads, and their consolidation is entirely devoid of any objectionable feature of monopoly. In the very nature of things, street railroads are seldom competitors in business. They were never known to compete in rates, and can only be laid on such public highways as the authorities may determine. The necessity for keeping some streets open for ordinary vehicle traffic keeps the street railroads sufficiently far apart as a rule as to eliminate any matter of choice on the part of the intending passenger. Each line supplies and accommodates its own peculiar territory, and there is no real choice, and hence no real competition. As to rates, these are universally fixed by the franchise ordinances. They are the same on all the roads, so that the intending passenger is moved in his choice solely by consideration of convenience to himself. In short he simply takes the line that carries him to his destination with the least inconvenience. Monopolies are only odious when of a character that they do or have the power to fix their own price for what they alone can sell. Not so with the consolidated street railway. So far from having the power to increase the cost of travel, consolidation always results in a practical reduction of cost by giving to the passenger the right to ride for the same single fare the increased distance brought about by the consolidation. No thoughtful man would condemn a street railway consolidation because it neither stifles competition nor increases cost of travel, nor creates a monopoly as that term is generally understood.

There can be no doubt that consolidations of this character are greatly beneficial both to invested capital and to the public at large. And, happily this is so, because the public is never so likely to have its wants provided for as when it is to the interest of capital to do so. There is no tie so strong as common and mutual interest. This is a principle which would render many conflicts and controversies impossible, if kept always in mind and strictly adhered to in all dealings between public service corporations and the municipality in which they dwell.

Digitized by Google

I commend it to the thoughtful consideration of all who are assembled in this convention as the firm foundation on which aggregations of capital may safely rest, the Gibraltar of justice and right, garrisoned by an always sound and healthy public sentiment, against which the assaults of prejudice, passion and demagogy would be hurled in vain.

A NEW CONSTANT-POTENTIAL CONTINUOUS CURRENT TRANSFORMER.*

BY F. W. DAVIES.

There are probably few electrical engineers, who have had much practical experience in the running of continuous current transformers but have realized the advantages of employing machines that would give a constant potential at all loads, thus avoiding the necessity of compensating for the voltage drop in the secondary at full load by means of a small "booster."

The writer's object is to describe, as briefly and concisely as possible, a simple method of compensating for the voltage drop in the secondary at full load, which he has discovered. This method is analogous in its effects to the "compounding" of a dynamo, and the winding of the same, like the series winding of a compound dynamo, may be so proportioned that the secondary voltage at full load is either less than, equal to, or greater than the voltage on open circuit, corresponding to the "under-compounding," "compounding," and "over-compounding," respectively, of a dynamo. It can

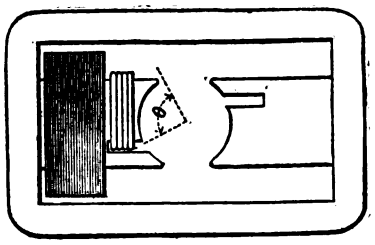

Fig. 1.—Showing Coils Removed from One Pole.

easily be adapted to existing designs, and as the writer has not protected it by letters patent, some engineers may possible consider it worth their while to adopt it. It is applicable only to transformers of the single field type, where both the primary and secondary armature windings are wound upon one core, and not to those machines which consist of a dynamo and motor mounted on one bedplate, with their armatures rigidly coupled together.

It is proposed to vary the ratio of transformation as the load increases by means of a particular arrangement of the armature winding used in conjunction with a special compensating winding on the field magnet; this variation in the ratio of transformation to be such that the E. M. F. in the secondary circuit shall be raised by the amount necessary to compensate for the loss in volts at the increased load.

For the sake of simplicity a two-pole machine is considered, the same principle being easily extended so as to include multipolar machines. The principle of construction is as follows: The field magnet may be of any type, but each pole must be provided with a slot in which the compensating coil is wound as shown (see Fig. 1). These coils must be connected in series with the secondary circuit, and connected up so as to assist the main magnet winding. Their function is to strengthen the flux in the magnet pole on one side of the slot and to weaken it on the other side; in other words, the object is to concentrate the lines of force of the field magnet within the area enclosed by the compensating coils. The armature is shown in Fig. 2.

To render the winding more clear only two coils, one primary and one secondary coil, have been shown. The primary coil is wound with any usual pitch, provided it is sufficiently great for the coil to enclose the whole armature flux when the coil is in the neutral position, that is with its plane at right angles to the field. The secondary coil, as will be seen, is chord wound. Its pitch should be such that it just encloses the lines of force which pass through the compensating coil, but it should not enclose any more than this. In other words, the angular pitch of the coil must be approximately the same as the angle θ (Fig. 1). A diagram of the complete armature, showing six coils in the primary winding and six coils in the secondary winding, is shown in Fig. 3.

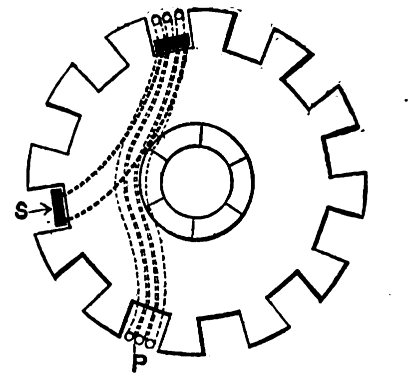

Fig. 2.

The action of the transformer is very simple. At light load when there is no current in the compensating coils, those lines of force which are embraced by the compensating coils, are usefully cut by both the primary and secondary windings, but the remainder (i.e., those passing through the small polar horn on the other side of the slot in the pole piece) are useless as far as the production of E. M. F. in the secondary winding is concerned, owing to the

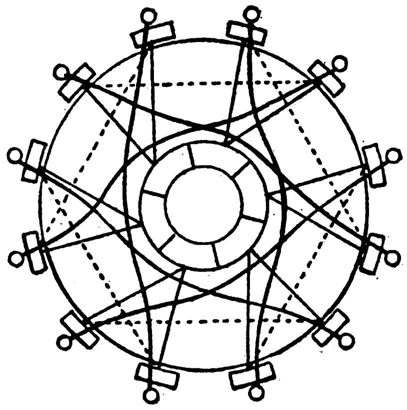

Fig. 3.
Winding Diagram Showing Connections at Secondary Commutator. Secondary Coils represented by rectangular bars; Primary by small round bars.

small pitch of the coils in the secondary winding (both limbs of a coil being under the same pole for a certain period in each revolution of the armature). This makes the ratio of the secondary volts to the primary volts less than it otherwise would be. But as the load increases the compensating coils begin to act. They divert some of the lines from the small polar horn and drive them through the polar area enclosed by the compensating coils, the total flux remaining practically constant. The result is that a larger proportion of the lines is usefully cut by the secondary winding, until at full load practically the whole of the flux is available for producing the E. M. F. in the secondary winding, and the ratio of transformation is then the same as the ratio of the total number of active conductors in the two windings, less the loss of the internal resistance of

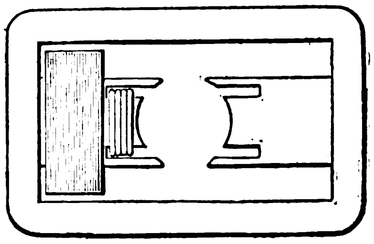

Fig. 4.—Showing Coils Removed from One Pole.

each armature winding. The effect of this is that the transformation ratio $\frac{\text{Secondary E. M. F.}}{\text{Primary E. M. F.}}$ is greater at full load than at light load, and by designing on these lines the pitch of the secondary armature winding and the number of turns on the compensating coils may be so proportioned as to give any desired rise of secondary E. M. F. at full load.

The above arrangement may, of course, be modified in various ways, although the general construction above described is probably the best. For instance, instead of the single slot

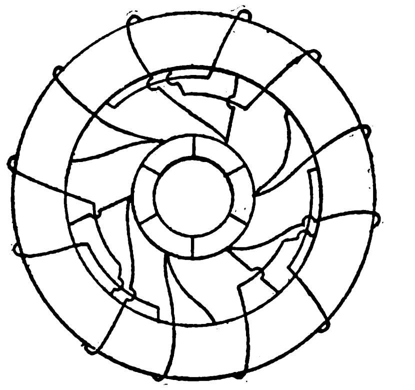

Fig. 5.

in the magnet pole shown in Fig. 1, two slots may be used, and the compensating coils wound in them, as shown in Fig. 4. The chief disadvantage with this construction would be that, owing to the weakening of the polar horns by the compensating coils, it would be difficult to get that essential for good commutation—a strong reversing field. Then, again, a ring armature may be employed in place of the drum armature if desired. In this case a winding of the secondary, similar to that shown in Fig. 5, might be used.

The invention above described can also be applied to machines having four poles and upwards: it being essential, of course, that the coils in the secondary winding are of such a pitch that they only embrace a part of the total magnetic flux at light load, the variation in the ratio of transformation from light load to full load being obtained as in the case of two-pole machines by means of compensating coils on the magnet poles. In any case, the principle of compensating for the drop in the secondary by means of varying the ratio of transformation—this variation being obtained by means of compensating coils wound on the magnet poles in the manner above described—remains the same.

SNOW AND SNOW PLOWS.*

BY RICHARD E. DANFORTH.

Our friend, the supply man, tells us that the proper time to consider the question of snow fighting apparatus is when the leaves are on the trees and the shirt-waist man is in evidence. Following this very proper suggestion, your attention is called to some of the problems connected with the removal of snow and ice, with the hope that a comparison of experience will lead to a general improvement in the appliances used and the methods followed in handling this troublesome substance.

It might be stated as a general proposition that street railways have, in their snow plow equipment, failed to keep pace with their improvements along other lines. A dozen years ago it was thought sufficient to equip passenger cars with 10-hp. motors. The severe strains placed upon these motors during the winter months caused the manufacturers to increase the capacity of motors from time to time, and this and other kindred reasons have led to the final adoption of motors averaging a capacity of 50 hp. each.

Passenger car bodies and trucks have increased in dimensions and weight so that it is not an unusual thing at the present day to see in daily service passenger cars 40 feet long, weighing, with motor equipment and trucks, 23 tons. Street railway managers and manufacturers have failed in many cases to realize that a car built to effectively remove snow from the tracks and ice from the rails must be heavier and equipped with more powerful motors than the passenger cars operating on the same lines. Five years ago a snow plant, equipped with two 35-hp. motors and having a total weight of 6 tons or 8 tons, was considered a fine piece of apparatus for removing snow. These plows, during heavy storms, and with the aid of one or more passenger cars as pushers, have been able to keep a few miles of track clear. Experience has shown, however, that the plow above referred to is not perfection.

Each manager, aware of the defects in his snow fighting apparatus, has endeavored to make improvements, with varying results. A road at one corner of the State copies the steam road rotary snow plow. A road at the other corner of the State builds share and nose plows of great weight, and still another road tries sweepers.

In comparing notes with our neighbors, it will be well to remember that conditions vary in the different cities and parts of the State. What might give most excellent satisfaction in Binghamton might prove most unsatisfactory in Buffalo, and might not be permitted by the common council in Greater New York.

It might be well to first consider the different kinds of snow which usually falls during the three or four winter months, and its effect upon the transportation facilities of the locality. It is generally conceded that a wet snow is a bad snow, and that systems having grooved rails are most liable to be blocked by this snow. A wet December snow falling in considerable quantity, before the frost has fully entered the ground, puts a most severe test upon the capacity of the transportation department to keep the cars of a system in motion.

The first few inches' fall melts as it strikes the rail, and, in melting, cools the same. By the time 6 inches have fallen, a coating of slush is formed over and about the rails, which, upon the passage of a wagon or other vehicle, whose wheels press out the moisture, becomes a coating of ice upon the rail and in the groove. The ordinary snow plow, equipped with gravity flanges or diggers, fails to make any impression upon this coating of ice, and usually lands in the gutter. With the usual equipment of one plow to from 5 miles to 10 miles of city track in streets where there is considerable wagon traffic, and the cars at frequent intervals, the result of the above conditions is a tie-up and a call for the track department with picks (and salt).

The Toronto Railway Company successfully meets this situation by equipping its cars with track scrapers, which are not only supplied with a steel flange of proper form for removing ice from the groove, but are connected so that a powerful leverage can be placed upon them when required. These track scrapers cut the ice from the rail as easily and smoothly as a planer takes a cut from a piece of metal. Properly adjusted, they can be run through switches and around curves with safety.

Experience has shown many of us the necessity of equipping all snow plows with devices having the same action as the above described track scrapers, but we have yet to learn that the best way to meet this condition is to equip our passenger cars so that we may at all times be sure of having a clean track groove.

When the thermometer approaches zero the conditions change. With fine, dry snow, which forms hard drifts but doesn't freeze nor attach itself to the rail, the difficulty then arises of obtaining sufficient traction between the frosted wheels and rail. Lightweight cars and plows make no headway without the use of sand, and at this time we find the advantage of weight in our equipment. The use of salt under these conditions but aggravates the case by the formation of slush, which sticks, and finally freezes, to everything it touches. Sand is but a makeshift, and soon causes trouble by filling up the grooves in the rail, and causing flat wheels; but it is of great service in keeping cars in motion, as well as in stopping them when under headway.

When the temperature is in the neighborhood of 20 degrees, the falling snow is usually feathery and light, and easily handled. Two feet of this snow doesn't cause the trouble that 6 inches of wet snow will make. The problem in removing this snow from the track during a heavy fall is one of having plows running at close intervals or those designed to remove from the track large quantities without delay. This snow drifts quickly and under a light wind. On lines operated through thinly settled districts and subject to large drifts, we find at this time a rotary of great value. A share plow will do the work perhaps more quickly during the first storm; but as the banks at the side become high and are frozen solid (unless carted away), the share plow is of little service, having no place to shove the snow, while the rotary picks it up and scatters it to a great distance.

A description of the various types of snow plows and snow handling appliances might well be given at this time. A relic of horse car traction is found in the walkaway plow, which is nothing more or less than a crude road machine drawn by horses, consisting of four wheels, a modified wagon frame and board. This machine proves valuable in leveling back drifts beyond the reach of electric snow plows.

The step from a walkaway to the leveler is but a short one, the leveler being merely a light flat car, drawn by power outside of itself, and having suspended under its body boards placed diagonally across the track.

Next in order comes the electric leveler, having its shares, or boards, placed diagonally under the body and between the wheels, the motive power being transmitted to the wheels through sprocket chains from motors upon the car floor.

Following steam railroad practice, plows are also constructed with a board placed in front of the plow proper and diagonally across the track, so that the work of removing snow is done in front of the car instead of being done under the car, as by the above described levelers. The first of these plows were blunt affairs, ramming the snow and forcing it horizontally to one side. A modern plow of this type is more carefully designed, the share being so constructed as to first lift the snow, and then roll it over and over until it is clear of the track. This plow is further equipped with powerful flanges and easily controlled long wings or flukes.

Sweepers in various forms have been in use for years. Many roads still use the rattan sweeper, with its pair of brooms set diagonally across the track, and driven by a motor placed in the cab. These sweepers will remove the snow down to the pavement, if run early and often, but are slow and fail entirely in a great quantity of rapidly falling wet or heavy snow.

Sweepers with steel instead of rattan brooms have been constructed and operated with some success. The advantage of this form of broom is found in its great strength and stiffness. The steel brushes will cut hard snow with great ease, do not bend, break or wear out rapidly. They are only stalled by drifts so high that the brooms cannot throw the snow out of the way. With them a drift may be bucked as successfully as with an ordinary share-plow.

Six years ago the first electric rotary snow plow was put in operation. It was a crude affair, having for its cutting blades a segmental screw, whose front view gave the appearance of a propeller wheel, and back of which was placed an ordinary fan blower with a suitable spout. A pair of light motors were mounted on the shaft in a small car to rotate this screw. A passenger car was used to shove this appliance along, and at the end of the road a pin was pulled and the plow body rotated on its truck, so that the plow pointed in the opposite direction; the passenger car was then placed behind the plow, which proceeded on its journey.

In the following fall the writer built a modified form of this rotary snow plow (under contract with the patentee), having its truck equipped with motors, thereby doing away with the necessity of a pusher. The ease with which this appliance cut through huge drifts, depositing the snow at a distance from the track, led the Buffalo Railway and other companies to construct similar plows, making the plows two-ended: by means of suitably arranged clutches, the blades at either end of the plow may be cut in or out. The cutting blades are also arranged so that they can be given a lead or pitch in either direction, and be rotated right or left-handed. By this arrangement it is possible to always throw the snow in the most advantageous direction. The motor equipment on each plow consists of two 35-hp. motors on the truck and two 35-hp. to 50-hp. motors on the rotary shaft.

A modification of this rotary, intended to

*Read at the convention of the New York State Street Railway Association. Buffalo, Sept. 18, 1900.

Digitized by Google

overcome inherent defects in the above described design, has been built at Charlotte. This plow has a twin screw, thereby getting the cutting blades down closer to the rails, and reducing the dead-snow load, which, in the former design, frequently stopped the travel of the plow.

The writer's experience has included work with all of the above-described general types of plows and sweepers.

In the city of Buffalo, situated, as it is, at the foot of Lake Erie, subjected to high winds, and having at all times a more or less humid atmosphere, these plows, rotaries and sweepers are rated and berated by operatives about as follows:

The walkaway is invaluable in leveling back drifts at a distance from the track, opening up gutters and walks, and in performing similar work otherwise requiring manual labor.

The leveler, or windsplitter, as it is here called, has no excuse for existing, beyond that of furnishing something to run through the streets when all the plows are crippled and in the shop.

The electric leveler leaves a beautifully smooth street, cleans close to the rail, but is no good when snow falls 6 inches an hour, for 6 inches of ordinary snow stalls it, unless a pusher is used. It can seldom be operated during the day with less than five men, and usually requires six or eight.

The heavy share plow, with compression flangers, high-curved shares, long, heavy wings or flukes and powerful motors meets all city conditions well. It fails between high, frozen drifts close to the track, and in cuts on suburban lines, because it has then no place to shove the snow, and, when built for double track, unless weighing over 19 tons, is liable to shove off the track in a hard-packed drift.

The rotary is of value in keeping lines open during a heavy fall of snow, through high snowdrifts and at times when all other plows fail.

It does not easily handle very wet snow, unless equipped with powerful motors. Its present design is faulty, but the faults might easily be overcome in new machines. In heavy work it must be moved slowly, with the fans rotating at very high velocity. It is an invaluable part of our snow plow equipment.

The rattan sweeper in this climate is too slow and expensive in maintenance. After trying one under varying conditions we have concluded that it is not for us, nor we for it.

The steel-broom sweeper ranks next the rotary. It cannot work as well in deep drifts, but excels in hard packed or wet snow. It frightens horses, and, therefore, is not used during the day in the business districts of the city. When these steel broom sweepers were built, W. P. 50 motors were the latest type out. These plows have therefore been equipped with these motors, and as a result made frequent visits to the repair shop. Hereafter these sweepers will be equipped with G. E. 1,000 motors, and will be expected to give more reliable, if not more satisfactory, service.

Anticipating your question, the snow plow equipment of the International Traction Company's interests consisted last winter of: One McGuire sweeper, two T. H. steel broom sweepers, one single-end rotary, eight double-end rotaries, seven heavy share plows, Buffalo pattern; two Taunton share plows, one Brill share plow, sixteen electric levelers, ten trailer levelers, ten walkaways. This equipment operated over 190 miles of track in Buffalo, 18 miles in Niagara Falls, 5.50 miles in Lockport, 10 miles in Tonawanda, 56.50 miles of suburban and interurban track, a total of 280 miles of track.

The organization for the removal of snow and ice in Buffalo covered 190 miles of city track, and 30 miles of suburban track.

The Buffalo snow plow equipment consists of: Four rotary plows, three sweepers, fourteen electric levelers, ten share plows, seven trail levelers (in reserve), seven walkaways.

Giving an average of one snow plow for each 5 miles of track, or one heavy plow and one light plow for each 13 miles of track.

The superintendent was the head of the organization. The assistant superintendent and the assistant engineer of the way acted as aids, each supervising the operation of one-half of the territory, which was further divided into twelve districts. Each district was under the personal supervision of an inspector. Each inspector controlled two or more snow plow crews, under a captain, and one or more gangs of shovelers, under a track foreman. The general track foreman had immediate charge of all shovelers, arranged their reliefs, furnished extra men and emergency aid of all kinds, and in all cases working with the district inspector.

By means of a private telephone exchange the two aids and the general track foreman, the superintendent kept in communication with the plows and men on each line. Inspectors reported by 'phone hourly, when possible, and in all cases kept the superintendent informed of their movements and the condition of their lines. The snow plow captains reported each time they passed a company telephone and otherwise from a public telephone, in case of accident to their plows, or when in need of aid.

At the first sign of a storm all snow plow crews, track shovelers and switch cleaners reported at the designated headquarters of their district. The walkaways and teams, with sleighs, were subject to the call of the inspectors through the superintendent. They were sent to the various districts as required, the foreman of teams supplying from outside sources the additional teams and sleighs required, arrangements for which were made before the first snow fell.

The inspectors, upon approach of a severe snow storm, saw that the snow plow crews were on hand, and if necessary, reduced the passenger car service to give the plows ample power and aid.

In case the snow plow equipment in a district was insufficient to insure the continuance of service on any line, aid was at once obtained from some neigboring district, instructions being transmitted by telephone or by one of the aids to the districts affected.

The aids and the general foreman were supplied with horses. During severe storms the instructors of motormen and conductors and clerks in the superintendent's office acted as special messengers, and when required, assisted the inspectors in operating the passenger cars and acted as substitute inspectors while the inspectors were resting.

Last winter's severe storms proved a hard test of snow fighting appliances generally, and Buffalo's experience satisfied the management, as well as the operatives, that one-half the equipment was useless in emergency, and that the traction of all plows should be increased, that each type of heavy plow, sweeper or rotary has its place, and is of value to the company only when given the class of work for which it is designed.

THE THREE-IN-ONE LAMP.

A lamp has recently been placed on the market by the American Lamp and Brass Company

FIG. 1.

of Trenton, N. J., which is unique and embodies features that are much to be desired. The

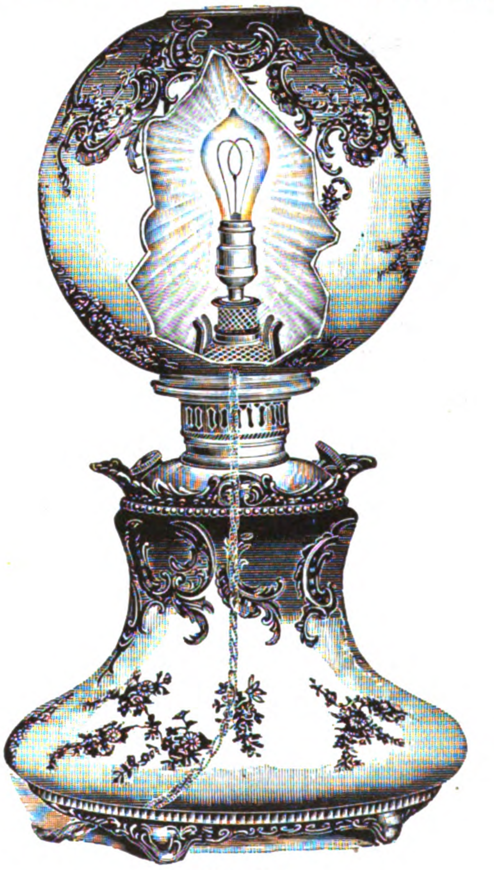

FIG. 2.

lamp referred to, known as the Three-in-One lamp, and shown in the accompanying illustra-

Digitized by Google

tions, permits of either electricity, gas or oil being used. Fig. 1 is a view showing the oil pot, burner and other parts as adapted for either oil, gas or electricity. Fig. 2 shows a lamp fitted for electricity in use, with a portion of the globe cut away. In Fig. 3 may be seen a lamp in which either oil or gas may be used. The peculiarity and great advantage of this lamp is that it can always be used for any of the three illuminating agents almost instantly so far as the lamp is concerned. If for oil it is only necessary to fill the fount. When gas is used connection is made with a gas burner or chandelier by means of a flexible tube and goose neck, the tube being passed up through the center of the oil pot and a special burner provided with a flame spreader different from the one ordinarily used with oil. The regular flame spreader of the oil lamp is removed and the gas attachment alluded to screwed on to the top of the gas tube when the lamp is ready for use. When electricity is to be used wires are connected with an electrical current and an incan-

FIG. 3.

descent lamp is attached. For gas it can be used with either an ordinary or Welsbach burner. These lamps are regularly made in a line embracing about 50 styles with hand-painted decoration varying in price from $12 to $30 each. Another line is handsomely decorated, but not hand-painted, varying from $1.50 to $15 each. In this connection they put up a combination of Three-in-One lamps each complete with 6 feet of rubber tubing, goose neck, burner, mantle and chimney, packed four in a case, having two distinct decorations, and are sold at $5 each, allowing but one package of four to a customer. This, it is said, practically gives the Three-in-One outfit gratis, as it is only the normal price of the lamps.

PERSONAL MENTION.

Mr. L. W. Gill, B. A. Sc., of Montreal, has been appointed lecturer in the newly created chair of electrical and mechanical engineering in the Kingston (Ont.) School of Mining.

Mr. Daniel M. Hall has assumed the management of the Rome (N. Y.) Home Telephone Exchange.

Mr. J. M. Jeffers, president of the Montrose Electric Light Company of Scranton, Pa., is perfecting arrangements by which the exhaust steam from the electric light plant will be utilized to heat the court house, school building and several business houses.

INCORPORATIONS.

The Chicago Motor Vehicle Company, Harvey, Ill. Capital stock, $1,000,000. Incorporators: H. W. Kellogg, W. C. Worth and W. B. Donaldson.

The Harding Incandescent Company of Illinois, Chicago, Ill. Capital stock, $250,000. Incorporators: A. L. Ringo, Gottlieb F. Mayrer and C. Knox Harding.

The Turtle Creek & Millerstown Street Railway Company, Harrisburg, Pa.—to construct and operate an electric railroad. Capital stock, $6,000. Incorporators: R. W. Williams, C. B. Wilson, W. F. Kimmick, J. W. Johnston, J. R. Montgomery, all of Turtle Creek.

The Electric Safety Traction Company, Boston, Mass.—to build and equip railways. Capital stock, $5,000,000. Incorporators: B. Gibby of Malden, L. Dixon of South Farmington, C. K. Corsant of Cambridge, S. D. Butterworth, Jr., and J. P. Swift, both of Boston.

The Lackawanna & Wyoming Valley Rapid Transit Company, Camden, N. J.—to operate transportation railways and to produce compressed air and electro-motor force. Capital stock, $2,850,000. Incorporators: F. R. Hansell, George H. B. Martin and William F. Eidell.

The Whitehall Gas & Electric Company, Whitehall, N. Y. Capital stock, $50,000. Directors: Thomas S McLaughlin, William S. McLaughlin and Brackett W. Burleigh, Whitehall; Oscar B. Weber and Edwin E. Wetherby, New York City.

The White Motor & Machine Company, Waltham, Mass. Capital stock, $25,000.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 30, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

660,738. Third Rail for Electric Railways. Benjamin C. Seaton, St. Louis, Mo., assignor of one half to Benjamin Eiseman, same place. Filed March 5, 1900.

630,779. Fender for Trolley-Cars. Lajos Madas, New York City, assignor of one-half to Adolf Stern, same place. Filed Aug. 17, 1900.

661,020. Electric Railway System. Byron E. Osborn, Anburn, N. Y. Filed Aug. 5, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

660,795. Electric Arc Lamp. Charles E. Harthan and George E Stevens, Lynn, Mass., assignors to the General Electric Company of New York. Filed Nov. 2, 1898.

660,852. Electrode for Arc Lamps. Frederick Hachmann, St. Paul, Minn., assignor of three-fourths to Louis Hill and Max Toltz, same place, and Elizabeth Baasen, Milwaukee, Wis. Filed Dec. 22, 1899.

ELECTRICAL MACHINERY AND APPARATUS.

660,561. Electric Indicator. Charles L. Clarke, Rye, N. Y. Filed July 10, 1900.

660,713. Electric Motor. Thomas S. Watson, Milwaukee, Wis., assignor to the Browning Manufacturing Company, same place. Filed Oct. 4, 1899.

660,724. Electric Conveying and Elevator Apparatus. George K. Fischer, Salt Lake City, Utah, and Frank Klepetko, Great Falls, Mont. Filed Aug. 24, 1899.

660,803. Measuring Instrument. Franz Schrottke, Berlin, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago Ill. Original application filed Sept. 2, 1899. Divided and this application filed Feb. 12, 1900.

660,804. Measuring Instrument for Alternating Currents. Karl O. F. Schrottke, Berlin, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Sept. 2, 1899.

660,818. Electric Switch. Charles H. North, Cleveland, O., assignor to the North Electric Company, same place Filed Nov. 15, 1899.

660,820. Magneto-Electric Generator. Charles H. North, Cleveland, O., assignor to the North Electric Company, same place. Filed Aug. 24, 1900.

660,907. Single-Phase Alternating-Current Generator. Benjamin G Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania Filed May 24, 1899.

660,908. Variable-Speed Electric Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed June 5, 1899.

660,909. Electric Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Sept. 14, 1899.

660,911. Alternating Current Induction-Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed April 14, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

660,572. Telephonic Apparatus. Raimund Gunther, Vienna, Austria-Hungary. Filed Nov. 18, 1898.

660,796. Hygienic Resonator for Telephones or Other Sound-Transmitting Devices. Gustavus Hoglund and Carl M. Hedman, Chicago, Ill., assignors of one-half to Charles Berg and Maurice Lundin, same place. Filed Dec. 18, 1899.

660,802 Telephonic Apparatus for Use on Vessels, etc. Mario R. D'Asar, Genoa, Italy. Filed Feb. 28, 1899.

660,826. Telephone Call Recorder. Harold D. Stroud, Chicago, Ill., assignor of one-half to James E. Plew, same place. Filed Feb. 23, 1900.

MISCELLANEOUS.

660,551. Electric Fan. John T. Beswick New York City. Filed May 8, 1900.

660,613. Process of Amplifying Electric Currents. Joseph B. Baker, Newton, Mass. Filed Nov. 23, 1899.

660,618. Device for Truing Commutators. Percy B. Bosworth, Akron, O., assignor of one-half to Frank G. Carnahan, same place. Filed Aug. 10, 1900.

660,620. Non-Interference Signal Box. Frederick W. Cole, Newton, Mass., assignor to the United States Fire and Police Telegraph Company, Boston, Mass. Filed Nov. 13, 1899.

660,633. Electric-Snap-Switch Cover. Monroe Guett, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company, same place. Filed June 27, 1900.

660,634. Rotary Snap Electrical Switch. Monroe Guett, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company, same place. Filed June 27, 1900.

660,741. Appliance for Making Metallic Connections Between Electric Conduits, Alfred W. Watkins and Rudolpf Lenk, New York City. Filed March 13, 1900.

660,801. Electrically-Operated Machine-Tool. John Riddell, Schenectady, N.Y., assignor to the General Electric Company of New York. Filed Aug. 30, 1900.

660,810. Coin-Controlled Mechanism. Frank P. Cox, Lynn, Mass., assignor to the General Electric Company of New York. Filed April 8, 1899.

660,815. Electric Distribution System. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 28, 1900,

660,816. Producing High Vacuums. John W. Howell, Newark, N. J., assignor to the General Electric Company of New York. Filed Aug. 31, 1899.

660,819. Magnetic Signal. Charles H. North, Cleveland, O., assignor to the North Electric Company, same place. Filed April 21, 1900.

660,836. Electrogalvanic Battery. Horatio J. Brewer, New York City. Filed July 7, 1899.

660,857. Electromagnetic Tooth-Stopping Hammer. Curt Ostmann, Breslau, Germany. Filed June 5, 1899.

660,878. Insulating-Support for Switchboard-Conductors. Gilbert Wright and Christian Aalborg, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Jan. 2, 1900.

660,884. Metal-Depositing Apparatus. Hermann R. Boissier, New York City. Filed April 4, 1900.

660,887. Screw Electric Contact Device. Charles Chevallier, St. Quentin, and Eugene Cadet, Peronne, France. Filed Jan 5, 1900.

660,910. System of Electrical Distribution. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed April 14, 1900.

660,930. Method of Varying Active Lengths of Electrical Conductors. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Aug. 21, 1897.

660,979. Electric Accumulator or Secondary Battery. Henri Weymersch, Paris, France. Filed Feb. 19, 1900.

660,987. Electricity-Meter. Paul Eibig, Berlin, Germany, assignor to Martin Behrendt, same place. Filed Oct. 7, 1899.

DESIGN.

33,466, Electric Bicycle-Lamp. Alexander C. Proudfit, Boston, Mass. Filed Oct. 2, 1899. Term of patent 14 years.

Digitized by Google

THE TELEPHONE WORLD.

Nickel-in-the-Slot Telephone.

A telephone company of Cleveland has succeeded in constructing an automatic telephone attachment, which it asserts, after months' of experimenting, it has found no method of "beating." The instrument has been adopted by the United States Telephone Company, and will soon be installed in a number of its long-distance pay stations throughout Ohio. There are four slots in the machine, one each for 5, 10, 25 and 50 cent pieces. When a five cent piece is dropped into its proper slot, one tap on a bell is heard by the central operator; and the use of the 'phone is limited to the amount of talk that sum will buy. A ten cent piece causes two taps on the bell, a twenty five cent piece one tap on a gong, and a fifty cent piece two taps. To use the telephone a lever at the side of the box is turned, and the coin placed in the appropriate slot.

Arrangements have been made to put in a telephone service in the Philippine archipelago. The Lambert Schmidt Manufacturing Company of Weehawken has been awarded a contract to supply $10,000 worth of telephone instruments and to ship them to Manila as soon as possible. The Government plan is to have the telephone service extended, not only throughout Luzon, but to connect Manila with as many other islands as possible

The Hagerstown (Ind.) Telephone Company has now completed its line to Economy, and branch lines are extended into every community around that town. Nearly every farmer has a box in his house, and it is said there is not a neighborhood in Wayne County that cannot be reached by every subscriber from his own home.

There is a movement on foot in Spencer, Mass. to start a rival telephone company to compete with the New England Telephone Company. Several business men are interested in the new scheme. It is stated that a company is willing to do business in Spencer, if 100 subscribers are secured The rate will be much less, it is claimed, than the present rate charged by the New England people.

The Athens (Tenn.) Telephone Company has just completed putting in a new system, and Athens now enjoys a complete and up-to-date line. The local system is connected with the long-distance and those having local 'phones do not have to leave their place of business to converse with any section in the country tapped by the American Telephone Company. It is a great convenience and help to the patrons of the local system.

The Anderson County (Ky.) Telephone Company, having won its franchise suit against the East Tennessee Telephone Company, is preparing to erect its lines throughout the county, thus connecting remote points of the county that have hitherto been without quick communication with the county seat.

Yazoo City, Miss., now has direct communication by telephone with Kosciusko, at which place good connection is made with Carthage, in Leake County, Starkville and other towns in East Mississippi. This is the result of the completion of the telephone line from Kosciusko to Ebenezer, Miss.

Wire thieves have been making things interesting for the Wisconsin Telephone Company. Three times within a few days the toll lines running out of Milwaukee have been cut, and large quantities of wire stolen. The lines were cut between Milwaukee and Waukesha and Fond du Lac.

The Bell Telephone Company of Kokomo, Ind., has reduced the residence rate to 50 cents a month on monthly contracts. The old rate was $2, which the new company met with a $1.25 schedule.

The Sioux Rapids (Ia.) Telephone Company is at work installing a complete local system. The company is composed of C. B. Mills, T. Tymeson, R. G. Hulett and P. J. Cilley, representative business men, and will begin business under favorable circumstances.

The long distance telephone line which is being constructed across the State of Washington, has reached Ellensburg. This system will be completed shortly.

Work on a new telephone line between Grand Rapids and Marshfield, Wis., has been commenced, It will be rushed and the line completed before December 1.

D. N. Tallman, president of the Minnesota Central Telephone Company, has completed a local telephone exchange at Raymond, Minn., with 28 local telephones.

The Cumberland people are at work erecting the poles and telephone ines for a local exchange in Crowley, La.

A Loud Speaking Telephone

Mr. Gregor Blanck, the Hungarian, who has invented a loud-speaking telephone, is at present in London negotiating with the British Postoffice and the National Telephone Company for the introduction of his instrument upon their system. The Postoffice has informed the inventor that if he can construct an instrument with which it will be possible to telephone a distance of about 1,000 miles with ease and without having to shout into the instrument, so that the words may be distinctly distinguished at the other end, they might be disposed to avail themselves of the invention. The inventor has been busily engaged upon a machine for this purpose, and by the aid of a very powerful inductive coil has succeeded in telephoning over a distance of 1,000 miles, and will shortly experiment with his improved instrument before the authorities of the postal department. The crux of the invention is that by means of the coil, articulation of the speaker is intensified as the words pass along the wire. Besides connecting the instrument with the telephone, the inventor will attach it to the electrophone, and by this means one will be able to sit in a room and listen to what is happening in a theater without having to insert the tubes into the ear, as is now necessary. The sounds would proceed from the electrophone in much the same manner as they are recited by the phonograph.

The Home Telephone Company of Lockport, N. Y., has begun work on its pole line for an exchange in that city. About twenty car loads of cedar poles have arrived, and will be rapidly set throughout the city. The service will be a copper metallic one, with no party lines. It will compete with the Bell Company, which has many ground and party lines still in use there. The local company will also build a toll line to Niagara Falls and Tonawanda, to connect with the local independent exchanges already in operation there. The new company is being cordially indorsed by the public.

Arrangements are being made in Charleston, S. C., to connect that city with all the sea islands lying thereabouts. Four submarine cables will be laid and the system will connect all the section with the long distance service. This system will be constructed by the Gordon Telephone Company, and controlled jointly by this company and the Sea Island Telephone Company, recently organized in Charleston. The Gordon Company entered the field against the Bell Company, and beat the Bell in the rush for the sea island connections, which will mean a heavy business. The Gordon will also have long distance lines, connecting with Columbia, S. C., Atlanta and Augusta, Ga. The intermediate points will be switched on, and the company will cut into the territory now held exclusively by the Bell Company.

A contract has been circulated among the physicians of Knoxville, Tenn., relative to the telephone war. As a result, it is claimed every physician, with the exception of a very few in that city, signed an agreement to use no other instrument in their offices for one year than that of the People's Telephone Company, at the rate which is now being charged. This action has been taken because the old 'phone company—the Cumberland Telephone Company—has increased its rates. The new or People's Telephone Company has bound itself in the contract not to increase rates for the specified time. There is much feeling existing in the city over the increase in rates for the old 'phones.

At a recent session of the council of Oklahoma City, Okla., an ordinance was passed granting the use of the streets to the Citizens' Independent Telephone Company for the period of twenty-one years. The council fixed a forfeit of $500 if the company does not accept the ordinance and complete the work within eight months. The company accepted the franchise, and the work will commence in about thirty days. The estimated cost of the exchange will be $30,000.

A telephone war threatens St. Johnsbury, Vt. The People's Company is fast completing its line, and will soon be getting the instruments located. There are over 200 subscribers at a yearly rate of $15, and the Bell people will have to meet this rate and improve its service to hold its subscribers. It is bound to be an interesting fight for the public, as it will lower the rates and better the service.

The Cincinnati Bell Telephone Company has increased its capital stock $1,250,000. Part of the new stock will be issued to stockholders as a dividend at the rate of two for five owned, and $510,000 goes into the treasury for future acquisitions.

Of the total number of telephones and transmitters under rental by the American Telephone & Telegraph Company, the Erie Telephone system on October 1 was using 292,336.

A Notice was recently issued by General Superintendent E. B. Smith, of the Iowa Telephone Company of Davenport, "to the holders of several thousand shares of stock of that company, asking them in accordance with their agreement to exchange their stock for stock in the Central Union Telephone Company and deliver their certificates to the cashier of the Citizens' National Bank. The stock will be receipted for by the cashier, and will be sent to Chicago to be converted into Central Union shares. The latter will be here in a few days and when delivered the Iowa Telephone Company will practically cease to exist. What effect this will have on the future of the Iowa Telephone Company no one here knows. It is understood that a progressive policy will be adopted by the Central Company."

The New York & Pennsylvania Telephone Company is preparing to establish a village telephone system in Dryden, N. Y. All the 'phones will be adapted to long distance service. This will be of great advantage to business men of Ithaca. The Dryden circuit will be under the direction of Manager P. A. White, of Ithaca. The company is also about to install similar systems in Groton, Freeville and Trumansburg in this State.

The contract has been let by the West Des Moines, Ia., school district to the Mutual Telephone Company of Des Moines to enlarge its service to include all the school buildings of the consolidated district. The company may have to put in a new switchboard in the office of the superintendent to accommodate the wires from the additional schools.

The rehearing of the case of the Northwestern Telephone Company against the city of Minneapolis, Minn., in the Supreme Court, has been put over from October 27 to November 29. It was the counsel for the telephone company that asked for more time.

President John M. Clark, of the Chicago Telephone Company, says recent tests show that operators answer calls from subscribers on an average of a little over six seconds from the time they are sent in and that it is expected to get the record down to four seconds before long.

The Paris (Ky.) Telephone Company, organized in Paris six years ago by local capitalists, has been purchased by the Columbian Telephone Company of Nashville, Tenn., which recently bought the East Tennessee system. The price paid has not been made public.

The case of the Southern Bell Telephone Company vs. the City of Richmond, Va., is not likely to be argued before the United States Supreme Court before next spring. It has been docketed for hearing. The Court is now in session and will remain in session until next May.

The business men of Alcester, S. D., are arranging for the establishment of a local telephone system.

The telephone line from Plantersville to Anderson, Tex., opened for business a short time ago. This puts Navasto, Tex., in immediate touch with every town and postoffice in Grimes County except three, but telephone lines will soon be built to these towns.

TELEPHONE INCORPORATIONS.

The Buchanan County Telephone Company, Independence, Ia.—to do a general telephone business. Capital stock, $50,-000. Incorporators: W. F. Roney, M. W. Harmon, J. F. Van Voss, C. E. Ransier, C. F. Bennett, all of Independence.

The Audubon County Telephone Company, Audubon Ia.—to do a general telephone business. Capital stock, $25,000. Incorporators: F. P. Hocker, W. B. Swaney, both of Audubon.

The Citizens' Telephone Company, Shelbyville, Tenn. Capital stock, $10,000. Incorporators: J. D. Hutton, S. J. McGrew, W. G. Evans, J. B. Frierson, Richard Sandusky, R. P. Shapard and Ernest Caldwell.

The Remsen & West Canada Creek Telephone Company, Remsen, N. Y. Capital stock, $2,000. Directors: G. E. Pritchard, Remsen; T. E Dunn, Port Leyden and C. C. Bullock, Northwood.

The Campbell & Rising Ville Telephone Company, Campbell, N. Y.—to connect with the villages of Thurston and Rising Ville. Capital stock, $1,000. Directors: Charles S. Smith and Clarence N. Risley of Campbell, and Emerson J. Jerry of Rising Ville.

The Monmouth Telephone Company, Monmouth, Ill. Capital stock, $25,000. Incorporators: Howard M. Carter, Sidney W. Worthy and Arthur Dyrenforth.

GENERAL ELECTRICAL NEWS.

Lighting.

Allegheny, Pa.—The Turtle Creek Electric Light Company has recently been formed here.

Arcadia, Ind.—The citizens of this town are agitating the question of electric lights.

Arcanum, O.—The Union City Company contemplates asking the council for an electric light franchise and contract for lighting the town.

Athol, Mass.—The Athol Street Railway Company has purchased land and water rights on Miller's River and will erect an electric light plant.

Braymer, Mo.—This place is working for electric lights.

Cambridge City, Ind.—The city authorities are endeavoring to build an electric light plant and pay for it in monthly installments.

Forreston, Ill—An electric light plant will be built here, which is to be completed by January 1.

Franklinville, N. Y.—It is stated that the electric light plant here is for sale.

Gaffney, S. C.—The citizens of this place recently voted for an additional issue of $15,000 of bonds to increase the electric light and water facilities.

Gastonia, N. C.—The Southern Railway Company of which F. S. Gannon, of Washington, D. C., is manager, will build a new depot at Gastonia to be equipped with electric lights.

Greenville, Ala.—This city contemplates the issuance of bonds for the purpose of erecting an electric light plant. C. E. Hamilton, mayor.

Green Cove Springs, Fla.—The Magnolia Hotel Company will install an electric lighting plant.

Hawkensville, Ga.—T. H. Grace, mayor of this city, wants prices on a complete outfit of electrical machinery for operating 40 arc and 1,500 16-candle power lights.

Kilbourn City, Wis.—The Kilbourn Machine Company has been granted a franchise for electric lights for the village.

Kokomo, Ind.—This city is making an effort to purchase the electric light and water plant at a cost of $80,000.

Lincoln, Neb.—A special committee has been appointed to secure estimates on the cost of putting in an electric lighting plant to be owned and operated by this city. Address Mayor Winnett.

Mattoon, Ill.—An explosion wrecked the electric light power house here causing $10,000 damage.

Monroe, Ga.—This city is negotiating for the purchase of an electric light plant here, and if not successful may construct a municipal plant.

Naperville, Ill.—An addition is to be built to the Naperville electric light plant. O. W. Strubler, city clerk.

Newbern, N. C.—Simmons & Hollowell Company of this place want estimates on the cost of dynamos and lamps for lighting.

New Baltimore, Mich.—The citizens of this place voted a short time ago upon the question of bonding the village for the purpose of establishing an electric lighting plant.

New Iberia, La.—M. T. Lewman & Co. of Louisville, Ky., has been awarded the contract for the erection of a new electric light plant here.

Oklahoma, Okla.—The electric light company of this place is putting in twenty miles of wire for the new street lights.

Orlando, Fla.—Bids are advertised for lighting this city with electricity.

Pewaukee, Wis.—A movement has been started to erect an electric light plant in this place.

Port Austin, Mich.—The citizens of this place have decided to issue bonds for $15,000 for the purpose of erecting an electric light plant. Bids will soon be advertised for. Address Geo. Murray.

Richmond, Va.—An electric light plant will be erected here to be owned by the city.

Ruston, La.—Bonds to the amount of $25,000 have been sold for the purpose of erecting an electric light plant and water works here. R. M. Adams, engineer, can be addressed.

Shelby, N. C.—The Shelby Electric Light & Power Company, recently incorporated, will build an electric ight and power plant.

Terre Haute, Ind.—The board of trustees of the State Normal School here has decided to ask the Legislature for an appropriation of $9,000 to be used in providing an electric plant for the school.

Tullahoma, Tenn.—The city council will pass an ordinance granting an electric lighting franchise to a private company. Address G. W. Davidson, mayor.

Washington, D. C.—The architects of the Indian office have completed plans and specifications for an electric light plant and wirings for the Chilocco Indian School near Arkansas City, Ark. Bids will soon be advertised for.

Street Railways.

Allegan, Mich.—Surveyors have been at work on the route of the proposed electric railway from here to Jamestown, which will connect with the Grand Rapids-Holland Road just begun. M. D. Owen of this city and D. Cornwell of Monterey are the promoters.

Baltimore, Md.—The Druid Hill avenue terminal car shed of the United Railways & Electric Company was lately destroyed by fire. The loss is estimated at about $25,000.

Billings, Mont.—J. McNaught, T. E. Collins and J. R. Haves are the projectors of a new railroad connecting rich mining country between this place and Great Falls, a distance of 200 miles. Articles of incorporation have been drawn placing the capital stock at $4,000,000. The company will employ electric motive power. Two large power houses will be built on the Missouri and Yellowstone Rivers.

Cedarville, N. J.—Nearly everything is now complete for the Bridgeton trolley road to be extended from here to Port Norris, and by spring the line will be run through.

Chippewa Falls, Wis.—The Chippewa Valley Electric Railway is to be supplied with power from the plant of the Chippewa Falls Power & Lighting Company. The railway company's plant in Eau Claire is insufficient to transmit power to drive the large cars up the hills in this city. The company's plant will be equipped with new machinery.

Cincinnati, O.—G. M. Gest, an electric railway builder of this city, contemplates building an electric line between Fulton and Union City, and probably to Tiptonville and Reelfoot Lake.

Easton, Pa.—It is thought that work on the trolley line between this city and Doylestown will be commenced in the near future.

Flint, Mich.—C. A. Beardsley of Detroit, appeared before the board of supervisors here and secured a franchise for the Detroit, Pontiac, Flint & Saginaw Electric Road.

Guadalajara, Mex.—It is rumored here that the street car company is negotiating with a view to providing its lines with electric power and doing away entirely with the horse or mule locomotion.

Matanzas, Cuba.—The municipality of this city at its regular meeting, resolved to receive proposals up to December 15 next for providing the city with electric or gas lighting, and with electric tramways; the proposals can be made to include both services of lighting and tramways or for each separately, the municipality reserving the right to accept or reject any or all proposals; the proposals must adhere to the essential conditions, contained in the specifications, which will be furnished upon application to D. Lecuonia, mayor. The specifications above referred to can also be obtained by applying at the office of Messrs. Jimenis & Co., 114 Wall street, New York City.

Mishicot, Wis.—The people of this and other villages along the proposed electric railway route are well satisfied with the prospect and will lend assistance in the promotion of the line.

Natchez, Miss.—Wilmer H. Shields of this city represents local and foreign capitalists who contemplate constructing an electric line here.

New Orleans, La.—An electric street railway is to be built from New Iberia to Berwick City. The distance of the new line will be 45 miles. A stock company has been organized in this city for the building of the road and Gen. F. F. Myles, 822 Gravier street, is at the head of the project.

Palmyra, Mich.—A franchise was lately granted to A. P. Southworth, as a representative of the Toledo & Adrian Electric Railway, through this village by the township board.

Ripley, O.—The work of securing the right of way for the electric road from this point to Hillsboro began recently.

Stamford, Conn.—A survey is being made for a new trolley line from the terminus of the Stamford road to Glenbrook. Construction work will be begun on the road before the cold weather sets in.

Uniontown, Pa.—The Tennis Construction Company of Philadelphia was recently awarded the contract for building the new electric road of the Uniontown & Monongahela Valley Railroad Company. The tracks will extend through the new Masontown coke fields, making about 20 miles of track.

Weymouth, Mass.—If a franchise is granted by the selectmen a new electric road will be built from South Weymouth to Holbrook, and from that place direct to Randolph and Dedham. The capital stock is $40,000. Drs. C. D. Harlow and G. D. Bullock of this town are on the board of directors.

Manufacturing.

Des Moines, Ia.—This city will probably have a manufactory soon that will make automatic electric switches for use on a street railway. H. S. Butler, general agent for the McCormick Harvester Company, has the matter in charge.

Wellsville, O.—The Modern Engineering Company of this place, has been formed for the purpose of manufacturing and selling mechanical and electrical devices. The capital of the concern is $10,000. The shares are $100 each and are held by Charles R. Dallas, Howard, L. Ken, G. B. Thurber and C. B. Reed, of Pittsburg, and Thomas Charlton, of Chicago, Ill.

Wheeling, W. Va.—T. B. Sweeney, E. M. Holliday, L. F. Stifel, G. Wise, J. L. Dickey and H. M. Russell, all of this city, are interested in a recently organized company, capitalized at $500,000, and known as the Poole Clock Company. The object of the firm is the manufacturing and dealing in electric clocks.

Company Matters.

Alton, Ill.—Trustee G. F. Crowe, for the creditors of the Alton Electric & Service Company, under the chattel mortgage, will sell the property of the company at public sale November 14.

Birmingham, Ala.—The Birmingham Railway, Light & Power Company will issue $1,750,000 in bonds which will be expended in improvements.

Middletown, N. Y.—The annual meeting of the stockholders of the Middletown-Goshen Electric Railway Company has been adjourned until November 15.

Vicksburg, Miss.—The Southern Light & Power Company has been organized with $100,000 capital stock to build, own and control electric light and power plants throughout the South. J. C. Schaefer of Chicago is the president.

Power and Transmission.

Raubsville, Pa.—The new electric power plant here will be completed and in operation by January 1.

San Bernardino, Cal.—The hope of Superior Judge Campbell, in using the waters of Lytle Creek for the generation of electric current is about to be realized and it is thought that before very many weeks work will be commenced putting the plans into execution.

Winchester, Tenn.—The Winchester City Electric Power Plant owned by M. L. McDowell & Sons was recently burned.

Winsted, Conn.—There is talk among some of the business men of this place about constructing an electrical power plant at the foot of the Lake stream near Meadow or Boyd streets.

Automobiles.

Trenton, N. J.—William Howard, the automobile manufacturer, is working on a plan whereby to perfect a racing machine.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

A Pittsburg, Pa., syndicate it is stated has bought the street railway system in Guadalajara, Mexico.

A Philadelphia paper states that Philadelphia Electric is being quietly absorbed by strong interests.

The Whitehall Gas and Electric Company has been incorporated at Albany, N. Y., with a capital of $50,000.

The stockholders of the Third Avenue Railroad Company, New York, will hold their annual meeting on November 14.

October gross earnings of the Easton, Pa., Consolidated Company's electric railway lines were $18,810, an increase of $2,840 over the same month last year.

The Welsbach Incandescent Gas Light Company of Philadelphia has declared a dividend of 5 cents per share, payable November 20, as registered November 1.

The Consolidated Traction Company of Pittsburg has declared a semi-annual dividend of 3 per cent. on its preferred stock, payable November 15 to stock of record November 6.

The New York Vehicle Company has taken possession of the plant of the Worcester Cycle Company, at Hartford, Conn., and will fit it up at once for the manufacture of automobiles.

At the meeting of the bondholders of the Newburgh (N. Y.) Electric Railway Company on October 25 a committee was appointed to consider and report to the bondholders at a subsequent meeting.

Officers of the Chicago Union Traction Company have decided to discontinue the publication of monthly reports of earnings, which began with their control of the North and West Chicago lines a year ago last July..

It is believed in usually well-informed quarters that in less than 30 days President Rossiter of the Brooklyn Rapid Transit Company will be succeeded by a Chicago man hitherto employed by the Whitney-Widener-Elkins contingent.

Chief Engineer Parsons of the New York Rapid Transit Commission has suggested a change in route of the Rapid Transit tunnel to pass under Forty-sixth street instead of Forty-second, from Park avenue to Broadway. The New York Central officials are considering the original plan of running the tunnel under the Grand Central depot.

Russell Sage and other authorities on elevated railroad affairs laugh at the report published recently to the effect that the Manhattan Elevated Company had failed to secure a right to lay conduits from its new power house across New York City to the several elevated lines to carry its electric power on the substitution of such power for steam. They simply say that all those details have been duly considered and provided for and reports to the contrary are purely sensational or for stockjobbing purposes.

The United Electric Company, of Toronto, Ont., successors of the Toronto Electric Motor Company and the Johnson Electric Company employs four times as many men as the two former companies did five years ago. The company has enlarged its premises three times during the past five years, and is now considering the doubling of its present plant. Evidence that the Canadian manufacturers have faith in the permanency of the present prosperity in Canada, is to be found in the fact that the company is installing many electric plants in factories for lighting purposes.

At a meeting of directors of the Boston Elevated Railway Company last week a statement was laid before the directors showing gross earnings for the year ended Septemper 30 of nearly $10,150,000. The company carried in round numbers 250,000,000 passengers, of which nearly 50,000,000 were free transfers. Earnings for the year ending September 30, 1899, were $9,671,440, an increase of $492,344. The increase the past fiscal year was $489,000, or about the same ratio of increase as the year previous. Net earnings for the past year have not been made up. If the same relative increase in operating expenses occurred the past year as in 1899, expenses must have been about $7,000,000, which would leave net earnings of $3,150,000 as compared with $2,844,290 in 1899.

The Athens, Nelsonville & Hocking Valley Traction Company is the name of a corporation which will ask soon to be incorporated under the laws of Ohio. This company has been organized for the purpose of constructing an electric road from Athens to Nelsonville, then to Murray City, the terminus of the road. At Chauncey, six miles north of Athens, a branch will be run to Gloucester by way of Millfield, Jacksonville and Trimble. The line will be 35 miles in length and will thus be connected with all the towns of the Hocking and Sunday Creek Valleys. One of the chief promoters of the electric line is H. H. Haning, of Athens, and he is backed by Dayton capitalists, prominent among whom are Thomas A. Selz, S. R. Pine, H. C. Haning and Robert Klein. The estimated cost of the line is placed at $600,000.

A representative of the leading copper producing interests of the country says: "The copper situation is in an impregnable position. The market is strong at 16¾ cents for both lake and electrolytic. I have never known the situation to be stronger. All the big producers, including the Calumet & Hecla, are sold out of copper. The Calumet & Hecla Co. sold its year's production last September at 16½ cents and it could not sell a pound of copper for delivery this year at any price for it has not got it. The stocks of copper abroad are now down to 21,000 tons, less than a months' production of the mines in the United States, and this copper abroad is of the poorest quality—the remains of the Secretan Corner. The consumption and production of copper are now running hand in hand and the demand is perfectly legitimate for it is apparent that consumers would not purchase copper other than for immediate needs at 16¾ cents. The supply cannot be materially increased for there are no new mines opened up worthy of comment."

EDITORIAL NOTES.

"Electricity's" Educational Series.

Elsewhere in this issue will be found the first of a series of articles of an educational nature, which was referred to in these columns last week. The topic this week is of an elementary nature and is entitled "Electricity and Magnetism."

It is the intention of the author to lead the reader in this series of articles step by step through the elementary stages into the practical application of electricity, so that the worker will, when the series is completed, have a clear idea of the relation of the theoretical to the practical. No mathematical gymnastics will be indulged in, the object being to place before our readers a concise, technically accurate series of articles on electrical subjects that anyone who reads them carefully can understand. We are not trying to educate such men as Nikola Tesla, Steinmetz, Pupin, etc., who, if anything, are overburdened with education as it is, but we are endeavoring to place before the practical worker in the electrical field, who has not had the good fortune or time to take a course in electrical engineering, matter that should prove of use to him in his everyday work and incidentally be a stepping-stone to a more responsible position. If our efforts result in but one electrician being benefited we shall feel repaid.

* * *

Two Automobile Shows.

The cry of "The King is dead, long live the King," might, at the present time, be twisted to "The automobile show is over; hurrah for the automobile show."

The exhibition of automobiles at Madison Square Garden, which began on November 3 and extended through last week, is now over, but the Grand Central Palace is just opening its doors, which will afford automobile enthusiasts a further opportunity of examining and commenting on the various up-to-date types of horseless carriages.

The Madison Square Garden show, which was held under the auspices of the Automobile Club of America, proved most successful, judging from the large numbers of people in attendance nightly. On the opening night the attendance was estimated at 9,000, which demonstrates in a most forcible manner the great interest that is being taken in this comparatively new mode of travel. Incidentally it indicates—what has been known for some time—that the automobile has come to stay.

In the number of the exhibitors, the almost endless variety of motor vehicles shown, in the whole scale upon which the first show of the Automobile Club of America was planned and carried out, there probably has never been its equal, at least not on this side of the Atlantic. More than seventy companies were represented, some from as far West as St. Louis. The exhibitors included manufacturers of the vehicles, makers of tires, and the many accessories of the machines. There were hundreds of vehicles and dozens of varieties, and the total value of them would run into the hundreds of thousands of dollars. The largest thing in the exhibit was a steam-propelled omnibus, weighing 60,000 pounds, with a seating capacity of eighteen. It is understood that a line of these vehicles will soon be operating in this city. Automobile stanhopes, trucks, coaches, victorias and cabs were everywhere in evidence, while, in what used to be the restaurant, could be seen several racing machines—the tricycle which won the Toulouse race in France, the Davis racer, the electric vehicle which won the fifty-mile race on Long Island last summer, and Dr. Lyman's racing machine propelled by gasolene, while in the foyer was the famous racing automobile brought to this country by A. C. Bostwick. This is the machine which won many races in France, and also the championship at the Tri-State Fair in New Jersey.

Among the curios was shown a steam-wagon made for pleasure purposes in 1860 and said to be still in good working order. It was made by Richard Dudgeon in this city, and it is now owned by his son, Frank P. Dudgeon, of Locust Valley, Long Island, who uses it at frequent intervals for the entertainment of his friends. It is practically a locomotive, with a coal-fed furnace, a boiler capable of withstanding 200 pounds pressure and an eight-horse power engine. The obstacle and climbing contests were most amusing and instructive and served to demonstrate that in competent hands the modern automobile is as docile as a well-broken horse.

From now on until November 24 automobile enthusiasts will have an opportunity of comparing the Grand Central Palace show with that recently held in Madison Square Garden.

Electricity and Fires.

In the issue of ELECTRICITY of July 11, 1900, we referred at some length to the hue and cry that was being raised in some of the daily papers over the large amount of property alleged to have been lost through fires of an electrical origin. At that time it was pointed out that, admitting that many fires were the result of faulty insulation, very frequently a conflagration is attributed to a defective system of wiring when, in reality, some other cause should be sought for. The recent Tarrant disaster has offered an opportunity for this subject to be brought up again, and, in fact, the building was still in flames when it was rumored that imperfect electric insulation was the cause of the fire. Whether this was the cause or not is not definitely known, and probably never will be, and yet we venture to say the fire will go on record as being one of an electrical origin.

When a fire does occur through a fault in the insulation of an electric light or power-wire the responsibility does not rest with the manufacturer of that wire, nor, as a rule, with the contractor who installs the system. When the system is turned over for use it may be in every respect perfect, and in nine cases out of ten it is. It is after the system has been in use for some time that a defect becomes apparent, and in most instances it will be found that this defect is caused by someone—not the contractor who installed the system—driving a nail through the insulation, or to the gnawing of rats, friction against a rough surface, or some similar unforeseen circumstance. Of course, where the wires are run in armored ducts the chances of damage are lessened, but some portions of the wiring are necessarily unprotected, and it is usually in such lengths that the damage occurs. This, then, indicates what we have pointed out time and again in these columns—the crying need of competent municipal inspection. A system of wiring may be electrically sound in every respect to-day, and through carelessness or what not, imperfect in a week, and if no inspector turns up to examine and find the fault no one is the wiser until a fire results. Then the dailies are afforded another opportunity of coming out with articles headed the "Danger of Electricity."

* * *

New York's Rapid Transit System.

Now that the Metropolitan underground railway of Paris after four years' of actual work is an accomplished fact, and now that English, German, French and American electrical concerns are, figuratively speaking, falling over themselves in an endeavor to secure the $25,000,000 contract for converting the motive power of the London Metropolitan District Underground Railway from steam to electricity, a few words regarding the progress that is being made on the underground rapid transit system in this city would seem in place.

After several years of uncertainty and red tape the contract for the construction of the rapid transit tunnel in New York was let about eleven months ago and work was seriously begun in April. The preliminary work consisted in removing, or rather changing, the course of innumerable water-mains and sewers. Then the work of excavating was actually begun at a point far up-town and in the lower portion of the city. The amount of money it will cost to build the completed tunnel is approximately $35,000,000, while the work already done is represented by $500,000, this sum having recently been paid to the subway contractor by the city controller.

The process of changing the water-mains and sewers is necessarily a slow one, and there is no doubt that as soon as this arduous preliminary work is accomplished the construction of the tunnel proper will be pushed forward at a very rapid rate. It has been fondly hoped that at least one section of the system would be in running order in three years, but judging from the many obstacles being met with it will be nearer five years than three before the citizens will enjoy the privilege of being taken home through the tunnel. That delays are inevitable is forcibly demonstrated in the stand just taken by the city authorities on the subject of pipe galleries under new Elm street. The plans called for suitable pipe and sewer galleries along the new Elm street part of the underground railway route, and at the eleventh hour the chief engineer of sewers of Manhattan Borough places his veto on the scheme with the statement that were the sewers located as proposed by the chief engineer of the Rapid Transit Commission they would be inaccessible. This stand necessitated stopping the work with a consequent delay which will probably occur again from time to time and as the city fathers see fit.

Work on the much-needed rapid transit system for this city will meet with sufficient delay in the ordinary course of construction, through unlooked for rock or quicksand, without unnecessary outside interference from the authorities in power.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

TELEPHONE men are on the *qui vive* for a decision on the Berliner telephone transmitter patent. The final arguments in the case were made over a year ago.

AMONG the many striking features in American export trade during the past three years, none is perhaps more pronounced than the record achieved by the manufacturers of electrical machinery and kindred lines. According to a table prepared by the Treasury Department the exports of electrical machinery increased from a value of $1,652,656 during the first nine months of 1898 to $2,090,787 during the same period of 1899, and to the enormous value of $3,987,405 during the nine months of the current year. The value of the exports of instruments and apparatus for scientific purposes, under which classification are included telegraph, telephone and other electric apparatus, shows a corresponding increase, the values for the periods named being $2,312,555, $4,101,014 and $4,849,789 respectively.

MR. JOHN M. ROACH denies that he will resign the presidency of the Union Traction Company of Chicago to accept the presidency of a Brooklyn electric road.

AN electric lighting board system has been brought out in England by means of which an incandescent lamp can be applied at any point with the certainty that it will light up. The "board" has a prepared face of cork and rubber, and below this there are wires, like a warp, embedded in a preparation of asbestos. Each lamp, or each wall plug, has two sharp pins projecting from its base, and when these pins are pressed through the surface of the "board" they make contact with a pair of wires (positive and negative) below and the lamp-lights. On such a "board" letters or words may be made by attaching lamps in the desired position, and the word may be altered as often as desired. The "board" may also be made as a moulding or filleting, and be run round shop windows, or the skirting boards of rooms and offices, or the interiors of show-cases. The arrangement of the lights is then completely under control and can be varied from day to day if desired. It is claimed that with "boards" of this nature short circuits are impossible.

TESTS are being made in Washington, D. C., of storm warning lights to be placed on the new signal towers recently authorized by Congress to be established in the principal harbors of the country. While the maximum of the present carrying capacity is about five or six miles, it is hoped to reach twelve miles at sea with the new oil lamps, and fifteen to eighteen miles with the electric lights in ordinary weather. American makers have protested against the award to foreign manufacturers, and Chief Moore of the Weather Bureau has decided that preference will be given to the American bidders.

AUTOMOBILES are put to a practical use in Webster City, Ia, by the Martin Telephone Company, which has adopted this means of transportation for linemen to go along the line and make investigations and repairs. It will save railroad fares and be far more convenient for the work.

ACCORDING to news received from London, Eng., the Postal Departmental Commission, which has been inquiring into the subject of wireless telegraphy will shortly report, after some months of deliberation, in favor of the earliest possible adoption of Marconi's system of wireless telegraphy by the postal authorities. The commission is also arranging as to terms for the acquisition of the Marconi patents, and negotiating with France and Germany regarding their attitude towards Marconi's invention.

THE car sheds and electric plant of the Norfolk Railway & Light Company in Huntersville, a suburb of Norfolk, Va., were totally destroyed by fire November 11. Fifty-two cars and the electrical machinery were demolished. The loss is estimated at $150,000, covered by insurance.

A NEW ORLEANS electrician says he has invented a phonograph without a cylinder or diaphragm, a phonograph that simply strings its records on a piano wire, as you might file so many written sheets of paper. When you talk over a telephone the vibrations of your voice send out a series of delicate electric waves. In the new machine a telephone is connected with an electro-magnet, which is excited by the little waves as they travel through it in infinitely rapid succession, and at the same time a long piece of piano wire is drawn past its two poles, very near, but not touching. This magnetizes the wire, but as the magnet itself is continually varying in power, owing to the vibrations, there is a corresponding variation in the effect it produces. That is, the wire is magnetized in different degrees all along its length, as if it were divided into millions of

Digitized by Google

very thin disks, each of a separate magnetic power. These disks are the record. For reproduction a mild electric current is sent through the magnet, and the same wire is again passed in front of the poles. The irregularly magnetized wire breaks the current into exactly the same kind of waves that were originally sent out from the telephone, and when an ordinary receiver is connected with it you hear a reproduction of the voice, just as you now hear it over the telephone.

WIRELESS telegraphic apparatus is now actually being erected at La Panne, Belgium, and on one of the Dover-Ostend mail boats, in order that communication between the ship and the shore may be continuously maintained.

THE British cadet-ship Conway has been fitted with new fire-extinguishing apparatus. A tank holding 4,000 gallons is fixed about 7 feet above the deck, but in addition, should a more powerful jet of water be required, pumps have been provided which can be driven either by electricity or steam. The motor is supplied from a storage battery charged by the ship dynamos, and the capacity of the cells suffices to work the pumps seven or eight hours at full speed, the battery already on the ship having been increased in size for this purpose. To deal with the increase of load a second dynamo has been added to the electric lighting plant.

OUR London correspondent writes that Sheerness and Shoeburyness garrisons are now equipped with wireless telegraphy apparatus for transmitting messages across the Estuary. This has been done for the purpose of increasing the efficiency of the arrangements for defending the entrances to the rivers Thames and Medway.

WHAT promises to be the first electricity station in the Congo district is soon to be started at the Roman Catholic Mission of Luluabourg, which is situated on the River Lubia, a tributary of the Kaosas River, which is itself a tributary of the Congo, says the London "Electrical Engineer." The head of the mission, who has for several years been in Luluabourg, is now proceeding there again, taking with him a dynamo, turbine, lamps, cables, wires, etc. He proposes to obtain the necessary power from a waterfall, the fall being some 28 feet high. The dynamo will light 150 lamps, and it is proposed to install 100 incandescent lamps and three arc lamps. The dynamo was manufactured by a firm in Charleroi, and the turbine is of French construction.

A NOVELTY in messenger call-boxes is about to be introduced in New York city. The new boxes, which will take the place of the familiar messenger calls, will each carry a telephone. In design they are circular, about eight inches in diameter, and carrying on one side a small lever, which is used when it is desired simply to call a messenger. On the other side is a hook from which hangs a telephone receiver, the transmitter being on the front of the case. There are no call bells, and, as at present arranged, the district messenger office cannot call up the house in which the box is installed. To call the district office the subscriber has only to remove the telephone from the hook when he can give his message, call the Police of Fire Department, send a boy on any desired errand, or, in short, hold any desired communication with the district office. The interior construction of the new boxes is very simple. They contain the usual train of clockwork and toothed disk running under a contact-making spring found in the ordinary messenger call, and, in addition, a small induction call for the telephone. There is no battery required on the subscriber's premises, the telephones working on the common battery system, in which the batteries are grouped at the district offices. The instruments are connected in series with one another on loop circuits running out from the district offices. So far no arrangement for interconnecting subscribers has been made, but, of course, the system may develop in the future. It is to be introduced in New York immediately. There are now 30,000 call-boxes and eighty-five district offices in the city.

MR. THOMAS A. EDISON has just perfected a new device for heating compressed air which, he asserts, at the same time utilizes all the store energy of coal and obtains fully 95 per cent. of it. "My invention," he says, "is a device for heating compressed air so that the losses in compression and utilizing as power are not only made up, but that it is possible to get power through air compression for less coal per horse power than through the steam engine.

A GERMAN contemporary describes a new type of storage battery switch which is designed to avoid the necessity of employing a booster to furnish the extra voltage for charging when the charging dynamo is required to provide current at the normal voltage for other purposes at the same time. The new switch effects this end by enabling two-thirds of the total number of cells contained in the battery to be always charged together.

AN interesting arrangement is being perfected at Ensley, Ala., for the operation of the two new batteries of coke ovens at Slopes Nos. 4 and 5 by means of electricity. The application will be made to the handling of coal larries, etc., for the purpose of putting the coal in the ovens and the power is expected to be furnished by the steel plant dynamos. When this is successfully accomplished the Ensley vicinity will be probably the only one in the South where such an arrangement is worked in the operation of coke ovens.

AN excellent method for examing the teeth is an electric dental lamp, which consists of a dry battery, connected with which is a small incandescent electric light that can be thrust in the mouth and illuminate the interior.

THE generating of electricity by means of wind power is receiving considerable attention in Germany and in a recent issue of the "Elektrotechnische Zeitschrift" it is stated that Mr. Gustave Couz, of the "Gustave Couz Elektricitäts Gesellschaft," in Hamburg, has been experimenting in this direction with promising results. A wind motor has been erected at the works of the company in question, which has a diameter of 40 feet and an effective sail surface of 1,070 square feet. The motor works at the rate of about 11 revolutions per minute, which speed is regulated by the automatic modification of the direction of the sails to the wind. With this motor an output of 1 hp. to 30 hp. and more may be obtained, according to the force of the wind, which power is transmitted to a 30 hp. shunt-wound iron-clad dynamo, designed to give 120 amperes at 160 volts terminal pressure when running at 700 revolutions per minute. The current generated by this machine is conducted to a switchboard and thence to storage batteries having a capacity of 66,000 watt-hours, or may be delivered to electro motors.

IT was announced last week that the directors of the Manhattan Railway Company of this city have adopted plans for the structure in which will be placed the machinery for the generation of electricity for the various lines of the system. All the large and more important contracts have been awarded, many have been completed and, while no official statement has been made, it is said that the entire Manhattan road will be operated with electric motive power by May of the coming year.

ADOLPH CRONE, a representative of the Prussian Government, and Carl Kratz, of Berlin, arrived in Pittsburg last week. They went there to inspect local manufacturing plants, and possibly to place contracts for machinery. Mr. Kratz represents some of the largest manufacturing interests of Dusseldorf, Germany, and he wishes to secure some of the advanced type of machinery, especially that operated by electricity. While in Cincinnati Mr. Kratz awarded contracts for $200,000 worth of machinery. Mr. Crone's mission is to visit the various industries in all of the large cities and make a report on the same to the German Government.

AN interesting experiment in conducting a Western ranch will be made this winter. It will be tried in Lower California and Mexico by Michigan people. Many of the old ranching methods will be done away with and in their place strictly novel and up-to-date ideas will be put in operation. The ranch is controlled by J. Dudley Morton of Pontiac and his uncle, T. Morris Flower, who has been ranching in Lower California for several years. The ranch will be supplied with all the conveniences possible. A unique feature of it will be the placing of several searchlights on the mountains overlooking the ranch, thus replacing the old system of night riding to prevent thieving. The tender of each light will be armed with a long range rifle and will also be provided with a signal code by which he can flash information to the other light tenders and any one who may be out among the cattle. Each light tender will also have at hand a telephone connected with the main ranch, the pushing of the button ringing an alarm bell. All parts of the ranch will be provided with telephone stations and an electric light plant will be installed at the ranch, all of the buildings being illuminated with electricity.

WHILE the electric arc is the most economical method of producing artificial illumination known, the violet-blue color of its light has always been considered objectionable. According to "Engineering," a German firm has attempted to alter the color, making it more yellow, like sunshine, by impregnating one of the carbons with salts of calcium, silicon and magnesia. As much as 50 per cent. of these salts imparts to the arc light the characteristic reddish yellow flame of the sodium. This combination carbon, only the upper one being of this composition, consumes more rapidly than the pure carbon rod, but this is overcome by making it of larger dimensions, so that even at the increased rate of consumption it will last just as long. Tests of the candle-power produced by such carbons show a remarkable efficiency.

'Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 1.

ELECTRICITY AND MAGNETISM.

A great majority of the young men in the electrical work to-day have got into it by accident, or in other words, were victims of conditions more than by choice of calling. The electricians who have chosen their line of work and have had the resources to prepare themselves for it by an engineering education constitute a small proportion of the electrical world.

The "accidental electricians" have encountered their ambition to succeed in the electrical world after they have become identified with the work and it is then they find the need of a technical education combined with their practical experience. It is to this class of electrical workers that these series of educational articles will be especially directed and in this way we hope to place the practical worker on an even footing with the engineer who has a technical course at his disposal.

I do not think it is necessary for us to go back to the early discoveries in electricity, when Dr. Gilbert found that not only amber but various other things had a peculiar attractive power when influenced by friction, and follow the course of its development through the various stages up to the present day. All this of course would be interesting reading, but we will leave it to the historian and take up our study of the science as we find it to-day. Electricity has become a part of our lives; we buy and sell it, use it for our convenience in a thousand different ways, and without discussing it theoretically it is best defined as a form of energy. By the word energy is understood the power of doing work, no matter by what means the work may be done. Knowing the fact that it is an energy, now picture in your imagination a substitute for this force which we cannot explain and for convenience sake in studying we will use this substitute of your imagination and call it electricity. You understand whereas electricity has an existence as real as the world around us, it cannot be touched by the organs of sense, consequently we use your mental picture until we delve far enough into the science to replace it with a better explanation.

Electricity is produced in a great number of ways but they all may be classified into some one of the following four classes:

First—By chemical action.
Second—By friction.
Third—By magnetic induction.
Fourth.—By direct application of heat.

BY CHEMICAL ACTION.

A good example of this means of producing the electric current is the ordinary battery. Towards the close of the last century, Volta and Galvani discovered that a current could be produced by chemical means. They found that when zinc and copper were immersed in acidulated water an electric current could be obtained in a conductor by connecting it to the two metals. This principle is what is now known as a primary battery and the current produced in this way is often called Galvanic electricity. There are a great number of different types of batteries used for producing current in this manner and an article will be devoted in the future entirely to them.

BY FRICTION.

The electric current is produced by expending energy in friction. The early discoverers in the science found that by rubbing amber it was made to attract light bodies. This was very mystifying to them and it is interesting to read the great number of theories advanced at the time to explain the phenomenon. This was among the first experiments of producing electricity by friction. A good example of this means to-day is the "glass wheel" frictional machine often used in colleges and laboratories, which apparatus is familiar to all. Another example, and one which is very familiar, is sometimes demonstrated by a swiftly running belt. You have probably often placed your finger close to a belt and noticed the blue sparks jumping across the space.

The frictional method, however, can probably never be of much service for practical purposes as the amount of current produced is so small, although the strength or intensity is great.

MAGNETIC INDUCTION.

This method is the one most generally used and is the basis of the modern dynamo. The principle is that any electrical conductor placed in motion within the influence of a magnet will have induced into it a current of electricity.

BY HEAT.

The possibilities of producing electricity by the direct application of heat has been demonstrated. To produce current in this way the ends of two strips of different metals are connected or soldered together and heated where they join; when their free ends are connected by a wire an electric current will continue to pass through the wire as long as the heat is maintained. Bismuth and antimony give the best results, but owing to their cost iron and german-silver are more commonly employed. As yet no thermal combination has been devised by which current can be satisfactorily produced for electric light or power. This principle, however, has the attention of some of the most eminent scientists of to-day.

MAGNETISM.

We cannot separate the study of magnetism from electricity, neither can we separate the associations which they bear to each other, for from either one we can produce the other in fact; where one exists the other does, or else the influence is there which is productive of it.

By magnetism you can produce electricity. By electricity you can produce magnetism. Magnetism has an existence as real as electricity and like it is not discernible by the organs of sense. You know while it is not perceptible by the organs of sense it exists; we see its effects, know how to produce it, use its influence in hundreds of different ways, and we call it magnetism, yet we cannot study a name for the thing itself, so consequently again resort to our imagination to supply a substitute as we did in electricity and use this for the purpose of studying it.

Magnetism is a condition produced by the influence of electricity. It is separated into two classes, or at least magnets are. Permanent magnets and electro magnets.

An object being magnetized and retaining that condition after the influence is removed which produces it, is called a permanent magnet. A good example of this is the ordinary horseshoe magnet. The various uses of this condition of magnetism we will encounter further on in our series.

An object which does not retain its state of magnetism after having been removed from the condition producing it is called an electromagnet. A greater intensity of condition can be secured in this style of magnets.

The quality of magnetism is that it will attract and hold fast anything which is made of iron or steel but has no effect on zinc, brass, copper, silver or gold, yet there is no visible change in the object magnetized. This earth has a north and south magnetic pole, so has every particle of matter if separated from its companions only in an imperceptible degree; now any magnetized object has the same peculiarities, that is, a north and south pole: one end of your magnetized article will be a north or positive magnetism, and the other end will be south or negative magnetism. These two terms are designated in the science by the sign + for positive and — for negative. Now comes the peculiarity of this wonderful condition. Either ends of your magnet will attract neutral iron or steel, that is, iron or steel not under the influence, but a + end of a magnet will attract the — end of another magnet and will repel the + end of it, so also will the — end of this magnet attract the + end of another while it will repel the — end of it, so we have the following rule to guide us. Like polarities of magnets repel each other while unlike polarities attract.

Permanent magnets are made by using hard steel, which after being magnetized several times will retain its condition.

Electro-magnets are made by using soft iron which will not retain its condition after being removed from the producing condition or after the influence is taken away. The great advantage of this kind of magnet is that a much greater intensity of the condition can be secured, consequently making it much more efficient for electrical purposes and also a great majority of instances where magnets are used are such that this style of magnetism is essential to the operation of the apparatus.

Article No. 2 will be The Laws of Induction.

LONDON NOTES.

(From our London Correspondent)

The Physical Society of London opened its new session on October 26 under the presidency of Dr. Oliver Lodge, F.R.S., who is now principal of the Birmingham University. There was a paper read by Dr. Shelford Bidwell on "Experiments Illustrating Phenomena of Vision" and an interesting discussion followed, Prof. Silvanus P. Thompson, the chairman, Mr. Blakesley and others taking part.

There then followed a paper on "The Concentration at the Electrodes in a Solution, with special reference to the liberation of hydrogen by electrolysis of a mixture of copper sulphate and sulphuric acid." The author was Dr. H. J. S. Sand. Dr. Sand in his paper derived an equation for calculating the concentration at the electrode of a solution of a single salt from which the metal is being deposited under the following conditions: (1) that the solution is contained in a cylindrical vessel bounded by the electrodes; (2) that no convection currents occur; (3) that the diffusion of the salt obeys Fick's law and its transport values are constant. This formula can be made the basis for roughly determining diffusion coefficients.

NOTES ON THE TESTING OF MODERN DIELECTRICS AT HIGH VOLTAGES *

BY J. WRIGHT.

In these days of electric light and power distribution at increasing voltages, the erstwhile familiar phrase of "— megohms per mile," as specifying the quality of the insulating medium or dielectric surrounding a wire or cable, is being rapidly superseded amongst manufacturers, consulting engineers, and others more or less directly concerned in these matters, by the resistance of that dielectric to disruptive discharge, in terms of the number of volts of E.M.F. to which the cable or wire is subjected before being brought into commercial use.

It is obvious, if we regard this matter in a practical light, that the change is materially for the better, and will benefit both manufacturer and customer, in that it denotes the true value of the dielectric as an insulating medium; a rubber-insulated wire, yielding an insulation resistance of some hundreds of megohms per mile under a testing E.M.F. of 600 volts continuous, may break down immediately under the application of 600 volts alternating, whereas a fiber or oil-insulated main, take, for instance, the Brooks semi-solid system of insulation, though yielding under test only a fraction of a megohm per mile, will withstand a pressure of as much as 20,000 volts alternating without perceptible change. Taking these facts into consideration it is obviously impossible to compare the merits of various dielectrics, or even various qualities of the same dielectric, in terms of megohms per mile, while, on the other hand, by subjecting two entirely different samples of insulating material to a high voltage stressing, or, as it is technically known, "straining," test simultaneously, at regular intervals of their respective "lives," it is possible to judge, with some degree of accuracy, their respective merits.

So important has this matter become, that in many cases specifications for cable contracts lay particular stress upon the resistance of the dielectric to disruptive discharge, the general rule being that it shall be subjected to a testing pressure or voltage at least double that at which it is ultimately intended to work for a certain predetermined period, and (here we have an important point) that the megohmic result obtained after this stressing or straining test shall evidence no perceptible deterioration in the insulating qualities of the dielectric.

To meet the increasing popularity of this form of test all the leading cable manufacturers have for some considerable time now provided the requisite plant for the purpose, such plant usually taking the form of an alternator yielding various low voltages over a convenient range, up to, say, 250 volts, which are then transformed by a suitable transformer, or bank of transformers, up to the required voltage, which may be anything from 1 to 20,000 volts alternating.

In order to undergo the test, the cable, if it be a simple rubber-covered core for example, is immersed in a tank of water with its extremities free, for a certain predetermined period, usually some 24 hours. A careful insulation test is taken on it in the usual manner by the direct deflection method, and the secondary (high tension) winding of the transformer is then connected to one extremity of the cable or core, and to the tank, respectively, the latter connection being usually made by means of an earth plate immersed in the water; the remaining end of the cable being left free. The alternator is then gradually speeded up until the voltmeter indicates the required voltage, which is maintained for the requisite period, after which the machine is gradually slowed down. It is better for all purposes to place two voltmeters in circuit, one across the terminals of the alternator, and the other (usually electrostatic) between the extremity of the core under test and earth, in order to indicate the exact voltage to which the cable is being subjected. If the multiplying power of the transformer be known, the one instrument then serves as a check upon the other.

It will be noted a few lines above, that special stress is laid upon the gradual slowing up of the alternator after the completion of the test; careful attention to this detail admits of an ordinary insulation test being made shortly after the stressing test. If, on the other hand, the voltage be suddenly cut off, in either the primary or secondary branch, it leaves a static charge in the core, which, more especially in a cable of high inductive capacity, tends to interfere with the subsequent galvanometer test, and requires the core to be connected directly with earth for a period proportional to that during which the high voltage was maintained, in order to dissipate itself.

In the case of a lead-sheathed or armored cable, the lead sheathing or other metallic covering, of course, takes the place of the water in the tank, thus rendering immersion unnecessary.

One point which has been noted in the stressing or straining of insulated core, especially where the voltage employed approaches that at which the limit of resistance to disruptive discharge is reached, is the apparent accumulation of potential at the points or extremities of the cable, which makes itself evident in the breaking down of the dielectric at the point where it enters or leaves the water, or, if dry, at the point where the lead or other sheathing ends. Various plans have been suggested from time to time to remedy this unfair distribution of potential, and to maintain it uniform at all points of the core. Probably the most likely one to have the desired effect is that of introducing a bank of lamps or other suitable high resistance between the free extremity of the core and earth, the number of lamps or other resistance being proportional to the voltage under application at the time. There would then be a complete circuit for the high voltage, while, at the same time, provided the plant were sufficiently powerful to maintain the potential under these conditions, that difference of potential would still exist uniformly at all points between conductor and earth, and all tendency to accumulation at the extremities would be prevented by the high resistance path to earth. The only drawback to such a plan is the enormous increase of power required, especially in the case of high voltages. High-voltage testing under normal conditions, in the case of cables of average inductive capacity, such as quarter-mile lengths of the ordinary 19 or 37 strands, for instance, requires the initial expenditure of anything up to 10 hp., and that on a blind or condenser circuit, whereas the adoption of a plan of connections, such as the one mooted above, would involve the doubling or even trebling of that output, and this in a factory turning out some hundreds of miles of various types of insulated core in a week, would be a material consideration tending to a general rise in the price of all cables and wires subjected to such tests—a condition of things to be, if possible, avoided.

Another difficulty in the way of successful high voltage testing is the efficient insulation of plant, and this more especially when dealing with voltages of 10,000 and upwards. There is no special design of transformer suited to the exigencies of cable testing, wherefore manufacturers in general have adopted one of the many well-known types of transformer on the market, and secured whatever extra insulation they could by insulating the case, oil-bath immersion, etc., all of which, though tending to the object in view, viz., the maintenance of a high potential, are highly unsatisfactory in that they are unreliable and open to breakdown at unexpected moments. Taking the question of oil-insulated transformers into consideration, it is obviously impossible to build an oil-immersed unit of any useful capacity for this type of work without proceeding to impracticable dimensions, whereas with the ordinary air-insulated types, unless great care be taken in their construction and erection, constant trouble is experienced in their breaking down at various unexpected points.

What is really required is a highly insulated type of transformer having a capacity of from 20 to 30 hp., capable of adjustment over a wide range of potential, either by subdivision or otherwise, which will enable voltages varying from 1 to 20,000 to be obtained at all times with perfect security from breakdown.

In the matter of actual testing there is no hard and fast rule as to the real voltage to be applied to any particular class of cable or wire, the general rule being that quoted above, viz., at least twice the normal working voltage; but conditions, of course, vary. With dielectrics of an impregnated fibrous disposition such as jute, paper, etc., the testing voltage may be in terms of the radial thickness of the insulating medium, always provided that the actual nature of that medium remains unchanged. With rubber-insulated core this rule does not apply, but depends to a large extent upon the quality of the rubber employed.

The old-time practice of "flashing" the live lead on to the end of the core was altogether an unfair and unsuitable test, in that it imposed enormous momentary potentials due to induction and kindred effects upon the core. The present system of steady application for periods varying from ten minutes to an hour, or even more, forms by far a more suitable method and amply guarantees the insulation of the core. To this end it is frequently specified that such tests shall be carried out like the ordinary galvanometer tests in the presence of the consulting engineer or his representative.

*From the "Electrical Review," London.

JAMES D. DEWELL, president of the Connecticut State Board of Trade, has just appointed a committee consisting of T. H. McKenzie, chairman, of Southington, Zalmon Goodsell of Bridgeport, William H. Matthews of Ansonia, Henry C. Rowe of New Haven and Francis Atwater of Meriden to act in accordance with a resolution passed unanimously at the recent annual meeting of the board. This resolution declares that the duties of the State Railroad Commissioners should be enlarged by delegating to them the supervision of the construction and operation of street railroads and railroads operated by electricity. The committee has instructions to favor this resolution at the next session of the Legislature.

THE PRESENT STATE OF WIRELESS TELEGRAPHY.*

BY PROF. A. BLONDEL AND CAPT. G. FERRIE.

In this paper the name "Wireless Telegraphy" is taken to refer only to the transmission of signals by means of Hertzian waves without the intermediary of conducting wires connecting the communicating stations. The history of wireless telegraphy may be briefly summarized as follows: In 1888 Hertz performed his famous experiments, but the absence of a sensitive detector did not permit him to think of distance signaling. In 1890, however, M. Branly discovered the principle of his "radio-conductor." This was re-named "coherer" in 1893 by Prof. Lodge, who in working with the instrument destroyed its temporary conductivity by a clockwork hammer. M. Popoff, among others confirmed the experiments of Prof. Lodge, and, in particular, made decoherence automatic by putting the coherer in series with cells and a relay which operated a circuit controlling the hammer. Later, Mr. Marconi applied M. Popoff's vertical wire "feeler," improved the apparatus for producing the waves—making the receiving and sending ends symmetrical—and modified for the better the construction of the coherer. Mr. Marconi also enclosed his apparatus in a metal screening-box, and employed numerous non-inductive resistances as shunts on the relay coils, etc., and thus protected his coherer from radiation produced either externally or internally to the screening-box.

The results obtained by various experimenters show the following facts: The distance which can be signaled across depends on the height of the vertical wires used, and is greater on sea than on land. On sea, in 1897, Marconi's instruments in the Italian navy covered 9 miles with vertical wires 70 to 100 feet long. In 1899, again, between Dover and Boulogne, a vertical wire 110 feet high sufficed for 26 miles. In the same year two vessels of the English navy communicated at a distance of 64 miles with wires 160 feet and 180 feet long. In 1900, Mr. Marconi spanned 77 miles with only 140 feet of vertical wire. In France, M. Tissot, using apparatus due to MM. Ducretet and Popoff, signaled over sea to a distance of 35 miles with vertical wires of 90 feet. In Russia, M. Popoff accomplished the same distance with wires of 180 feet. Captive balloons and kites have been employed on land for suspending vertical wires. Thus Dr. Slaby, in 1897, with wires of 910 feet long signaled 12 miles; M. Voisenat, in 1898, accomplished nearly 6 miles with 120 feet; and Mr. Marconi, in 1899, signaled successfully between Salisbury and Bath, 31 miles, using high kites. Lastly, M. Lecarme, in 1899, established communication between Mont Blanc and Chamouni, and found that a free balloon with a wire of 150 feet could communicate with the sending wire (120 feet long) when at a distance of 5 miles, and at a height of about 2,400 feet.

The law connecting height of vertical wire and distance of good signaling has been given by Mr. Marconi, and confirmed by Mr. Gavey, as $H \propto \sqrt{D}$. Moreover, the heights of the sending and receiving wires should be the same and the wires should be parallel. The authors' own experiments confirm these statements fairly well, but point out that the heights may be simultaneously varied within certain limits so long as their sum is kept constant.

Theory of Wireless Telegraphy.—The authors discuss, briefly, the various theories which have been proposed to explain exactly the action of the emitting on the receiving vertical wire. Then, after referring to a former paper by one of them (Blondel), which showed that the vertical wire oscillator is equivalent to a semi-oscillator of the Hertz type, they proceed to offer the theory which seems to them to be best. The electrical oscillations spread up the wire and agitate the ether round the wire. From there the waves spread through the surrounding ether; the lines of electrostatic force being in planes through the wire and abutting normally on the earth, the lines of magnetic force being circles having the wire as axis. These lines of magnetic force are especially abundant near the surface of the earth in consequence of the well-known concentration effect in the propagation of waves along conducting surfaces. But the concentration does not prevent the loss into space, in the form of hemispherical waves, of a large portion of the original energy.

The receiving wire being cut at divers heights by the spreading circles of magnetic force becomes the seat of oscillatory electromotive forces which act on the coherer. The longer the wire the more circles of magnetic force cut it, and the stronger the effect on the coherer. Guided by this theory the authors have tried experiments when the capacity of the oscillator was much increased and the self-inductance much diminished. The apparatus was then, virtually, a plate condenser with a very short vertical wire, and with this arrangement medium results were obtained.

In discussing the apparatus used in the production of the waves the authors remark that little progress has been made, owing to the exclusive attention paid by experimenters to the receiving apparatus. It is known, however, that the induction coils employed should be as powerful as possible, the sizes most used being those giving 10 to 16 inch sparks between points. Of course between balls, with the balls attached to wire and earth, the spark becomes reduced to 1 inch or 2 inches. The kind of interrupter used in the primary of the induction coil seems to matter little in practice. The authors have tried an alternating-current transformer supplying a pressure of 30,000 volts and above, and one of them has had built recently a new unipolar type of transformer giving a pressure of 100,000 volts. But the use of high-voltage transformers is limited by the fact that they are dangerous and absorb a great deal of power. In all cases it is found that the material of the vertical wire is almost without influence on the signals, that complete insulation—say, by ebonite suspension—is very necessary, and that covered wire may, perhaps, be useful, in that convective leakage is prevented by the insulation; but far the most important factor is the height of the vertical wire.

In the receiving apparatus considerable improvement has taken place, especially with regard to the coherer. To explain the action of the coherer, M. Branly supposes that some modification or orientation of the molecules take place through the action of electric force. Dr. Lodge attributes the diminution of resistance to welding between particles in contact. Whatever the intimate cause of the phenomenon of "coherence" it has been shown by one of the authors (May, 1900) that a coherer, in circuit with cells and a galvanometer, coheres when the potential difference at its ends exceeds a certain amount which has been named the "critical voltage." This voltage must not be exceeded by that of the cells plus that due to the self-induction of the relay circuit in the wireless telegraph receiver; and since the "critical voltage" is higher with the more oxidizable metals it is advantageous to employ filings of the less oxidizable metal. To keep the filings in the same state of oxidation it is advisable to exhaust the space between the electrodes. To alter the pressure with which a filing presses its neighbors, M. Tissot uses magnetic filings, and moves to and from the coherer a magnet whose lines of force are parallel to the tube.

It was natural, as in telephony, to attempt to transform the received impulses up to voltages more suitable for detection. Mr. Marconi uses such a transformer and calls it a "jigger." Its secondary is wound in layers containing successively fewer turns, and is included in the the relay-coherer circuit. The authors' experience of the "jigger" is that the small central condenser added by Mr. Marconi as an attempt to realize syntony has no perceptible action in this direction. According to Mr. Marconi, the "jigger" increases the distance of signaling by 30 to 60 per cent.

Among those things to which investigators should pay attention, the authors mention spontaneous decoherers. M. Tommasina has endeavored to replace the hammer decoherer by a magnetic decoherer, but unfortunately the filings of the coherer ultimately become so magnetized that the "critical voltage" is greatly lowered. The same experimenter has stated that good auto-decoherers can be made with certain kinds of microphone carbon powder. MM. Ducretet and Popoff have used steel powder successfully for a similar purpose.

Other detectors have beed tried by Righi, Tuman and others. One of the present authors has used a Geissler tube containing two large electrodes almost in contact, but found it less sensitive than the filings coherer. M. Neuzschwender makes a detector by taking a strip of mirror and dividing the silvering by a slit. If the arrangement be breathed upon so that some moisture is deposited on the slit a current of some magnitude can pass. The incidence of electro-magnetic radiation, however, diminishes very greatly the current passing. With this "anti-coherer" M. Bela Schafer has covered 34 miles, using wires 90 feet in length.

Telephones as detectors have not been very successful. They would undoubtedly be useful if put in series with a cell and a rapid auto-decohering coherer. With the extreme sensibility of the telephone, coherers of very low "critical voltage" could be used.

One of the gravest practical disadvantages of wireless telegraphy arises from the fact that messages dispatched from any station may be read by stations for which the messages are not intended. To overcome this difficulty Dr. Lodge and Dr. Muirhead have developed a syntonic system in which the receiving coils and capacity are tuned to the period of the emitting apparatus. Mr. Marconi has used earth connected wires placed near the vertical wires and parallel to them, in order to attain tuning. M. Blondel proposed, in 1898, a synchronization system in which a telephone with a certain frequency of vibration selects the radiation emitted from a vertical wire charged at the same frequency by means of an interrupter. Lastly, M. Guarini Foresis has, while putting forward some erroneous theories proposed a system of automatic relays of which the results are not yet known.

ELECTROLYSIS IN TELEPHONY.

BY P. KERR HIGGINS, A.M.I.E.E.

Text books tell us of the vast amount of decomposition, which takes place in the depositing bath; but, this must not be confounded with the electrolytic action between street car rails and lead cables (in the ground), as the actual damage done in the case of the latter is only about 11 per cent. of that which takes place in the bath. In the former the best conditions are established, in the latter, possibly the worst. That this is true has been time and again demonstrated by tests made under almost all conditions. It is to be regretted, that lead exclusively used for cable sheath is so susceptible to electrolysis, but this cannot be helped, and all that can be done is to prevent the action. It is a known fact that decomposition of iron pipes, by electrolytic action, almost entirely ceases after the current has been flowing in the same direction for some time, while in the case of lead, it is practically continuous while the current is flowing. The use of vitrified tile for conduits reduces the damage to the minimum, while exposed cables, or those in iron ducts, receive the maximum amount of damage due to electrolysis. It is very necessary when a lead sheath becomes damaged, even slightly, that a careful diagnosis should be made as to whether the trouble is due to electrolysis proper, chemical action or natural gas. In case of gas, the lead will show a very decided navy blue color, and the indentations will be uniform and not deep. This latter phase is also characteristic of chemical action only,

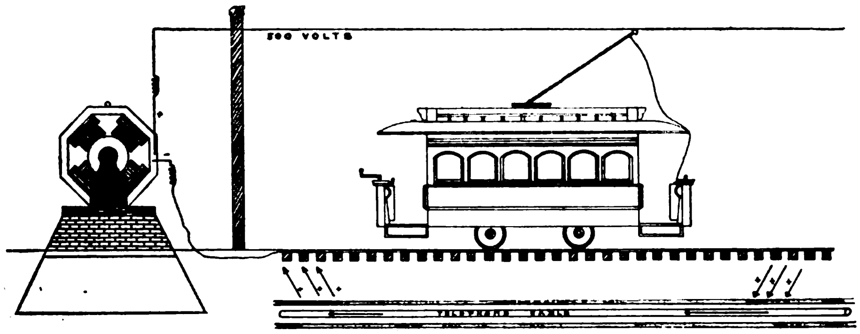

Fig. 1. Condition Before Remedy.

the lead retains its natural color. If due to gas, the leakage should be reported to the gas company, repaired, and ducts well ventilated. If due to chemical action, the lead, where exposed, should be protected, and, if possible the action neutralized, by painting the sheath with asphaltum paint, or applying grease, as the necessity of the case may demand. Should it be due to electrolysis, however, the first thing to do is to understand the cause, then test for the weak spot or spots and apply the remedy. The primary thing to do, in seeking to neutralize electrolysis, is to clear the system of all actual metallic contacts and leave it free, except for leakage; then proceed to drain the system, but this must be done in such a way as not to induce more current from the rails, and can only be done by making the tests as here given, or similar ones. In the installation of underground systems, greater care should be taken by engineers and others in charge of the work, to avoid paralleling the street car tracks, and they should *never* cross under them, as this is where the greatest amount of leakage takes place. In most, if not all cities, the positive (+) pole of the dynamo is connected to the trolley wire, and the negative (—) to the street rails. We have then a positive current passing along the trolley through the car to the rails, the intention being that the current, or the greatest portion of it, will return to the power house by means of these rails and be neutralized; probably it does, but enough, however, escapes through the earth to paralleling conductors, such as water pipes, gas pipes, lead cables, etc., in proportion to the ratio of conductivity which these offer to the path of the current. These afford a ready return back to the station, and it is here the damage is done. This action will

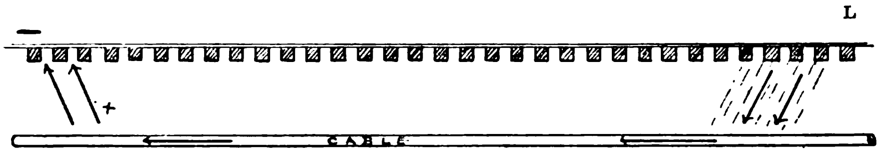

Fig. 2.

be readily seen in Fig. 1, where cables are exposed (or bare) in the ground; there will be found, at or near the points of leakage, fine threads of lead in the earth between the rails and the cable or pipe (L Fig. 2); but, where they are protected with conduits, etc., this is not observed. Occasionally, however, one may find fine particles of lead in the duct when considerable damage has been done. If a voltmeter and ammeter be now connected at this point of leakage (as in Fig. 4) and readings noted, it will be found that a current of high amperage and low voltage is passing from the rails to the cable, probably sufficient to cause damage. To obtain the amount of current which may have leaked into the cable system, take voltmeter and ammeter readings separately and together, and apply the following formula where—

V = voltage with ammeter cut out.
V_2 = " " " " in.
A = ammeter reading, } $V_1 - V_2 : V_1 :: A : X$.
X = required amount. } Formula.

The average EMF. found is about 8 volts, and the amperage from 80 to 100. These tests were

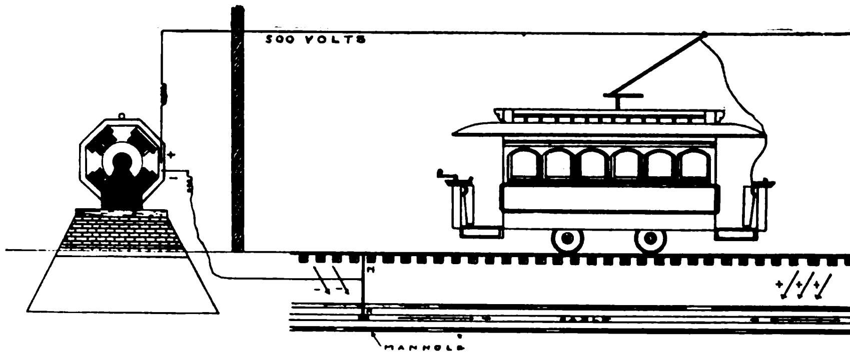

Fig. 3.—Condition After Remedy is Applied.

made when the station load was from 1,550 to 2,100 amperes. The size of the return feeder of the street car system generally runs from 400,000 to 500,000 circular mils, and where the construction is good a large amount really goes back to the power station as originally intended. Lead sheath of cables, such as now used, are supposed to carry safely from 150 to 200 amperes, but it is safer not to carry any at all, and they should at least be in a condition not likely to cause any damage, that is a negative state as opposed to the positive, coming from the rails at point of leakage. Now if we continue our tests (Figs. 4 and 5) along the route back to the power house, we will obtain results which will indicate to us the direction and amount of the current for example, an increasing current will denote that we are still receiving current from the rails, whereas a falling current will show current coming from the power house. By observing this closely we will reach a point where there is absolutely no potential, that is, the point of saturation where there is no tendency for the current to pass from the rails to the cable, or vice versa (see N Fig. 3), this is the point we have been seeking and will be referred to hereafter as the neutral point. We now connect or bond all our cables together, making the entire system one unit; this is done in order to reduce the resistance of the path back to the power house, and also to ensure the protection of points which might have escaped our notice. This bonding (which should be done with 1¼" strip copper tinned) having been completed, we come back to the neutral point at nearest manhole and connect our cable system to the rails at this point. Now, as a rule, this would be sufficient protection if the load on the street car system was uniform throughout, but, inasmuch as it is extremely variable, we are obliged to protect ourselves against all conditions which may arise, and we do this by running a special low resistance return wire of No. 00 or No. 000 insulated copper wire from the neutral point back to the power house (in addition to the connection from cable system to rails), and connect it to the negative bus bar there.

The conditions, after the remedy has been applied, can be readily understood by referring to Fig. 3, where N is the neutral point, and the conditions shown are verified by the tests made with the volt and ammeters. I have in my mind several places where these conditions have been established, and existed for several years, and absolutely no damage has been found during that time, whereas other companies, operating in the same city, but who took no special pains to overcome the damage due to leakage from the rails, have frequently had to take out sections of cable

Digitized by Google

almost entirely eaten through. Communities having asphalt streets with cement bottoms under the street car tracks sustain less damage than those not so provided, as these improvements render the ground more or less waterproof, and so protect the cables, etc.; but the ground is frequently made a better conductor by the presence of gas and salts in the earth proper. It is therefore absolutely necessary in making tests, to take into consideration the resistance of the earth under two conditions—moist and dry.

A method of finding the places where the leakage is greatest, which has proved very accurate and useful, is to have a test car (provided with water resistance), go over the route (after all the cars have stopped running), arranging stops to be made at certain intervals of time and have the current shut off at these stated periods, thereby having recording ammeters connected up at the station (as in Fig. 6) R to rail and C to cable a record can thus be had, and a list drawn up from it, showing that the amperage increased or decreased between certain points at a certain time, indicating less or more resistance to ground at these points; in this way the weak points, low resistance along the route may be readily located. We then go over the route, which the test car passed over, and compare the low resistance points on the chart with the route of our cables, and see whether the low resistance is due to close proximity or actual contact of our cables, or is due to foreign contact, such as water or gas pipes, etc. It is well in this connection, to watch carefully all contacts in manholes between gas or water pipes and cables, as also all contact between cables and iron braces, fenders, or manhole covers, as these frequently cause trouble, more especially when these latter are in contact with the street car rails, as is

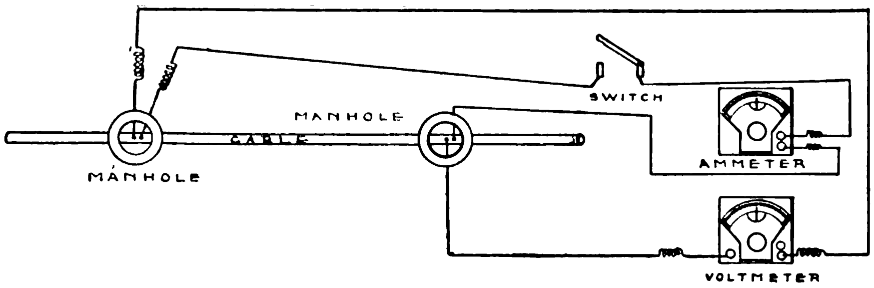

Fig. 4.—Voltmeter and Ammeter Tests can be taken Separately or Together as Desired by This Method.

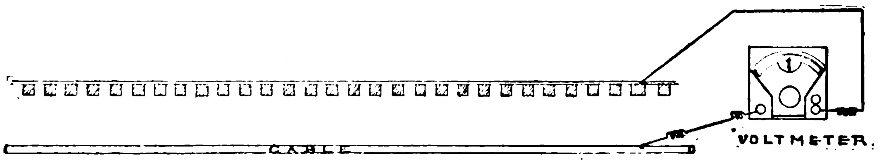

Fig. 5.

frequently the case. It may safely be expected, that if these conditions are established, properly maintained and frequent examinations and tests made, that electrolysis (so far as telephone cables are concerned) will be a thing of the past; but, as already stated, great care must be had in keeping the cables absolutely clear of all foreign metallic contacts, and more especially with the street car rails, except at the neutral point, as only in this way can the remedy be successfully applied. When cables rest on iron hooks, or supports in manholes, they should be protected by placing between them and the supports, sheet lead covered with asphaltum cloth and painted with asphaltum paint; wooden blocks painted also serve well as supports. All manholes should be kept clean, well drained and ventilated to prevent the accumulation of water and gas, which prove injurious to life and limb, and is certainly injurious to the cable sheath, apart from increasing the possibility of leakage. It will be observed, in many cases where tests are made, that a peculiar accumulator effect presents itself, if (for any reason) the power should be suddenly shut off, the ammeter showing a current flowing in the opposite direction to that flowing when current is on. In the case of lead cables this is very marked and registers often as high as 10 to 15 amperes, dissipating itself gradually. This should be watched carefully, as it may cause confusion in making tests. When dealing with the street car people it is well to approach them in a conciliatory manner and not to antagonize them. In this way I have always found them willing to assist me in making tests and connections, but when they are obdurate, and absolutely refuse any concession in the way of tests and contacts at power station and rails, then the only alternative is to go before the council, explain the damage being done and have an ordinance passed, compelling them to grant the privileges desired. I am satisfied, however, that this will seldom be necessary if the companies are approached in the proper manner, as they are generally familiar with the necessity for protection.

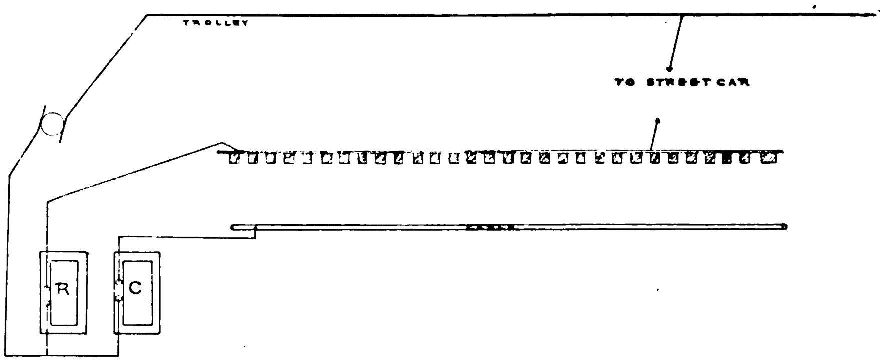

Fig. 6.

Some wrought iron girders in a building in Chicago had to be cut during repairs to make room for a steel column, and it was decided to use electricity instead of the old method of sawing. The girders to be cut were six in number and 14 inches deep with a one-inch web. To accomplish the work it was necessary to melt about 225 holes in the girders, and the actual time spent in cutting all was 3½ hours.

THE NEW POWER HOUSE OF THE BRISTOL TRAMWAYS COMPANY.

[From our London Correspondent.]

Toward the end of the year 1895 the Bristol Tramways & Carriage Company equipped a short section of its lines for electric traction. Much importance attached to the event, because it constituted the opening sentence in the great chapter of electric traction development which has been occurring in England during the past five years. Tramway authorities at that time were unable to recognize what benefit would be certain to follow the conversion, and hence the experiment, as it was then considered, was watched closely to see what was going to happen. The advantages which actually resulted on the electrical section were far and away beyond even those which the company's engineers themselves anticipated. It was not long ere opposition to the trolley gave place to a great demand for its extension, and several new sections have since been brought into service. Municipal fads and fancies hindered the company very considerably in the carrying out of its wishes to adopt the trolley system for the entire tramway service, and it is only at the end of the year 1900 that this has been accomplished. In the course of a week or two now the large power station at St. Philip's Bridge, on the River Avon, will commence the supply of energy to the lines (about 50 miles) upon which somewhere about 250 cars will operate. Some notes of its equipment, which has been carried out on up-to-date lines, will be timely.

The works' site is of course arranged advantageously in the matter of coal and water supply. The engine room is on the ground floor and the boiler room vertically above.

The boiler room contains eight horizontal water tube boilers, each with a capacity of evaporating 8,250 pounds of water per hour, at a steam pressure of 160 pounds. Each is fed by an electrically driven mechanical stoker of the "Coking" type, and the ashes are removed by the return line of the conveyor, and received into a tank outside the building, from which they can be drawn off into barges. The coal supply is received from barges by automatic shovels and delivered into a cold storage tank at the back of the building, from which conveyors of the American noiseless gravity bucket type now becoming usual in large traction power stations (as at Dublin, Shepherd's Bush and Chiswick), deliver the coal into the bunkers above the boilers; from these the supply is drawn off for the furnaces through weighing hoppers. The economizer, which has 360 tubes in 36 sections, is located (together with two 6,000 gallon water tanks) on the floor above the boiler room.

The building itself is steel frame, 140 feet

long, 52 feet wide, and 93 feet in height from the basement to the roof trusses. A 25 ton electrically driven crane traverses the whole length of the engine room. The smoke stack which is at the end of the boiler room has 10 feet clear inside diameter, and is 200 feet above the foundations. It is built up of steel plates in rings lap-jointed and riveted, tapering upwards and finished with an ornamental cap. It is entirely self supporting, lined throughout with fire brick.

The engine house contains vertical cross-compound engines with cylinders 22" and 44" x 43" stroke, running at 90 revolutions per minute; each is direct-coupled to a 500 kw. generator with a 16 feet fly wheel. The steam consumption of the engines is guaranteed to be 12.7 pounds of steam power per I.H.P., with a mechanical efficiency of not less than 92 per cent. The power station is centrally located and energy will be distributed on the continuous current principle. The generators are of the 10-pole type to generate 1,000 amperes at 500 or 550 volts as required. There are also two lighting sets, consisting of two 2-crank tandem compound high-speed engines, running at 400 revolutions per minute, and each having direct-coupled a 50 kw. 500 volt lighting generator. There are also three motor generators each of about 40 kw. capacity for use in connection with the rail return.

The condensing apparatus consists of two surface condensers of the Admiralty type, each containing 3,200 square feet of cooling surface. These are located on the engine room floor. There is a set of vertical twin type air pumps for each condenser. The circulating pump for each condenser is a motor-driven 8" centrifugal pump. This portion of the condensing plant and the auxiliary steam piping are located in the basement. The vertical compound duplex type boiler feed pumps are in the boiler room. The hot well consists of a cylinder 96" long x 48" diameter, and is located in the basement. The water from this hot well is raised to the water tank on the economizer floor by two electrically driven three cylinder pumps.

The switchboard is erected on a raised gallery at the bridge end of the engine room. It consists of white marble panels 8 feet high and 2 inches thick, bolted to angle iron frames. There are four generator panels, two lighting generator panels, three booster panels, 16 feeder panels, one lighting circuit and one meter ditto.

One point of particular interest in connection with this system is that whereas under the Board of Trade Traction Regulations a difference of potential of seven volts is permitted; on the Bristol line the potential difference between the points of the uninsulated return farthest from and nearest to the generating station does not now exceed from 2 to 3 volts. Very special attention has been paid to the bonding of rails so as to avoid electrolysis troubles. The rails are fished together with no less than five plates, one on each side of the web, in the usual manner, and one covering the entire underside, and two strips on the upper side of the bottom flange of the rail-bolted up with 14 bolts. The rails are double bonded at each joint with copper bonds $\frac{7}{16}$th, inch diameter, electrically connected to the web of each rail. There is also a third electric connection formed by Edison's plastic bond, fixed between the rail and the fish plates. Double cross copper bonds each $\frac{7}{16}$th inch diameter are fixed at 120 feet intervals. The bonding is stated to have cost about 7s. per single joint throughout. In addition to these arrangements, negative boosters are also rendering great assistance.

The engineers of the Bristol system are Mr. J. Clifton Robinson (to whom we have to acknowledge our indebtedness for certain of the particulars given in this article), and Mr. H. F. Parshall.

LEARNING TO BE A MANAGER.

Among a given lot of men up for examination there will be found various kinds and degrees of talent. One will be skillful with his hands, as, for example, in mechanical employment or in penmanship: another will be quick at figures; another will be expert as a salesman; still another will succeed in trading. One will have high qualifications as a bookkeeper or accountant, and still others will be faithful to any trust of a subordinate character reposed in them. The one kind of talent, however, that will be hard to obtain, and for which, accordingly, a high market price will be paid, is that of planning and direction, or what is commonly designated as executive ability. It is safe to say that there will be found one hundred persons able to do things under directions to one who is able to plan what to do and set himself or others at the doing of it.

To be able to wind one's self up and set one's self going is a talent in itself, and in the market conception of the case is worth much more than any other phase of individual talent. To be able not only to keep one's self advantageously employed, but to direct the labor of others, is still more valuable. Who is there among men in general more helpless than the individual out of employment, skillful to a degree in certain lines and yet for the time utterly unable to find anything useful to do? The tendency of the times is in the direction of division of labor and specialization. In offices, as in factories, men are trained to certain duties and are held to those duties, to the exclusion of everything else. When, finally, one of this class is thrown out of his regular line and is forced to depend upon his own resources, he is in a sense more helpless than a child. What, then, can be done to overcome this tendency and to render men in general better able to take care of themselves and to become self-reliant and equal to the common emergencies of life?

The fault in many cases is fundamentally that of temperament or habit. The boy looks forward to a certain line of employment as being that which will give him a livelihood, and with the feeling that when he has become skillful in his chosen vocation he will have done all that it is necessary to do. Here some friend ought to correct his planning. Every employment, sooner or later, fails those who are dependent upon it. Conditions change, panics occur, the demand varies. A friendly tip to the young man, therefore, would be, "Learn your trade by all means, but remember that you cannot depend upon it under all conditions. While holding yourself to it as the principal object, do not shut your eyes to other things alongside of it; for example, to adaptations and to variations, an acquaintance with which may be of considerable importance to you, first or last."

But the advice should go further: "Do not for a moment suppose that you have done all that is required of you when you have done one thing, however thoroughly. Do not feel that when you have learned one trade that you have earned the right thereafter to shut your eyes to all responsibilities, save only its requirements, and devote your time to frivolities. Instead, keep on learning, keep on trying, and always have an alternative upon which you can depend in emergencies." It is all summed up in the advice "think and study." While doing one thing learn to do something else by utilizing the time that would otherwise be wasted, for there is more recreation and more real enjoyment in study and planning how to do than in all the frivolities and so-called pleasures of life.

In thus learning how to do more than one thing, the young man will learn in part how to put himself to work. In thus giving attention to something else besides the routine of his daily labor the young man will learn how to adapt himself to varying conditions, and this is one of the first lessons in management or executive work. With an idea in mind of what he would himself do, facing unusual and unexpected conditions, he is, in part at least, prepared to tell others what to do under like conditions, and so, step by step, he gets to the position of a director of work instead of a doer of work. We can by no means exhaust the thought that is in mind in the brief space that can be devoted to such a subject. A volume would be necessary to do it full justice. At least one thought that is contained in these remarks, properly understood, will be of advantage to many of the younger readers of this journal, and that is this: To learn to be a manager, both of self and others, should be the worthy ambition of all.—"Ironmongers' Chronicle," London.

LEGAL NOTE.

In the recent case of Cloverdale vs. Edwards the Supreme Court of Indiana held that where electric light poles and wires were erected in a street under a resolution of the city council, which gave such permission, but expressly reserved "the right to revoke this grant and demand the poles to be removed and remove the same if necessary," the members of the council and the city attorney were not liable in damages for ordering such poles and wires removed after the electric light company's contract to light the street expired, and that, as the owner's business, if destroyed by the order of removal, was destroyed by an order which the council had a right to make, he could not recover damages for its destruction.

SOCIETY NEWS.

The New York Electrical Society.

The 209th meeting of the Society will be held at the College of the City of New York, 23d street and Lexington avenue, on Friday, November 16th, at 8 P. M. Mr. C. P. Steinmetz will lecture on "Alternating Current Engineering." The subject will be treated from the practical standpoint, and the lecture will furnish a complete survey of the tendency of the time in the whole field of electric light, power, and railway work. Mr. Steinmetz occupies a pre-eminent position in this important department of electrical work, and his utterances are received on both sides of the Atlantic with the utmost interest and attention. The lecture will be one of the most important ever delivered before the Society.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

Mr. W. T. Steward, electrical engineer, says in a communication to the Mayor of Toronto, Ont., that if the Board of Control will postpone the letting of the street lighting contracts for the city for the space of two weeks, that he will engage to "bring in Americans representing several millions of dollars of capital, who will make a proposition to light your streets at a saving of from $40,000 to $45,000 per annum over and above any proposition heretofore made to the city." The city of Vancouver, Mr. Steward states, is saving $12,000 annually in its street lighting bill as the result of having acted upon his proposition, and he exhibits a recommendation from the Mayor of Vancouver corroborating this statement.

The report is current in Toronto, Ont., that negotiations are nearing completion for the amalgamation of the Canada Cycle & Motor Company and the National Cycle & Automobile Company, the two companies recently formed by the amalgamation of several Canadian cycle and motor companies. Such an amalgamation as the one now projected would practically control the whole Canadian cycle business. The report is not denied by officials of the two companies concerned. The Canada Cycle & Motor Company is capitalized at $2,500,000, and the National Cycle & Automobile Company at $2,000,000.

Mr. James Ross, vice-president of the Montreal Electric Street Railway Company, has just returned from a two months' visit to England. Seven years ago Mr. Ross, along with a number of other American and Canadian capitalists, became largely interested in the street railway system in Birmingham, England. For years they have been endeavoring to induce the municipal authorities of Birmingham to allow them to introduce an electric trolley system in that city. It was only a few months ago that this permission was secured, and Mr. Ross states that the first part of new electric line will be opened for traffic about the first of the coming year.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended November 1:

Antwerp, 36 cases, $4,425; 3 cases electric motors, $332; Argentine Republic, 142 cases, $10,110; Australia, 283 cases, $19,526; 12 cases motors, $520; Birkenhead, 19 packages motor trucks, $3,450; Brazil, 13 cases motors and parts, $2,230; 55 packages, $2,309; 16 cases, $2,116; Bremen, 6 cases, $617; 1 box crane trolleys, $300; Bristol, 11 packages $500; British East Indies, 11 packages, $298; British West Indies, 15 cases, $455; Central America, 34 cases, $341; Chili, 44 packages, $1,875; Cuba, 19 packages, $463; Dutch Guiana, 2 cases, $40; Glasgow, 64 cases, $1,554; 10 rolls cable, $2,729; Hamburg, 29 packages, $4,217; Havre, 34 packages, $889; 1 case, $48; Hayti, 2 cases telegraph supplies, $65; Liverpool, 18 cases, $13,318; 43 packages, $5,489; 60 packages trolley poles, $1,511; London, 27 cases, $908; 106 packages; $7,992; Manchester, 1 case motors, $30; 341 packages, $26,500; Mexico, 82 packages, $781; Peru, 24 cases, $624; Santo Domingo, 240 packages, $1,987; Southampton, 8 packages, $178; Uruguay, 1 case, $95; Venezuela, 1 package, $14.

The following are the exports of electrical material and machinery from the port of New York for the week ended November 7:

Antwerp, 7 cases, $1,573, Argentine Republic, 30 cases, $3,648; 260 packages, $4,902; Australia, 23 cases, $660; Brazil, 14 cases, $1,273; British West Indies, 10 packages, $153; Central America, 67 packages, $1,989; Chili, 2 cases, $58; Cuba, 45 cases, $2,797; Ecuador, 1 case, $41; Fiume, 2 cases, $206; Genoa, 326 packages, $31,252; Glasgow, 187 cases, $11,681; 1 case electric instruments, $70; 114 packages, $3,950; Hamburg, 196 cases, $30,964; 30 packages, $2,334; Havre, 10 cases, $825; 145 packages, $3,621; Hayti, 1 case, $36; Leeds 6 packages, $170; Liverpool, 131 packages, $12,996; 1 package trolley material, $18; 2 crates trolley wagons, $337; London, 31 cases, $3,316; 177 packages, $14,247; 1 crate automobiles, $550; 16 boxes motors, $1,536; Mexico, 107 packages, $7,622; Milan, 146 packages, $12,056; Naples, 475 cases, $20,545; Newcastle, 20 cases, $4,000; Peru, 14 packages, $788; Porto Rico, 30 packages, $997; 1 reel wire cable, $124; Southampton, 6 cases, $650; Uruguay, 29 cases, $671; U. S. Colombia, 7 packages, $380; Venezuela, 38 packages, $636; Vienna, 35 cases, $8,151; Zurich, 7 boxes motor parts, $600; 7 cases, $600.

PERSONAL MENTION.

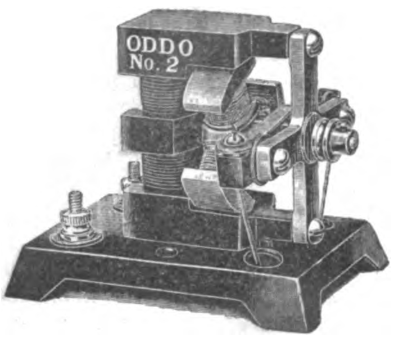
Mr. L. B. Stillwell has been appointed electrical director of the New York Rapid Transit Subway Construction Company. He will have charge of everything pertaining to the electrical equipment and construction of the Rapid Transit Railroad and has already entered upon his duties.

Mr. C. J. Heath, who for the past two years has been the local manager for the Postal Telegraph Company at Pine Bluff, Ark., has been promoted to manager of the company's office at Galveston, Tex.

Mr. Stanley Bartlett of Binghamton, N. Y., has accepted a position with an electrical manufacturing company at Lynn, Mass.

COMMERCIAL PARAGRAPH.

The "Oddo" Junior, the motor shown in the accompanying illustration, which is manufactured by the American Oddity Company, 170 and 172 West Broadway, New York, is according to all accounts, finding a ready sale at the price of



$1. This little piece of electrical mechanism may be used advantageously for many purposes, especially as it will run on one dry cell, making the cost for current almost nil.

INCORPORATIONS.

The West Chester Lighting Company, Port Chester, N. Y.—to manufacture and supply gas and electricity for lighting streets and public and private buildings in villages, towns and cities of the State. Capital stock, $2,500,000. Directors, Charles W. Squires, Charles H. Werner, Richard F. McKintry, Nathan D. Daball, M. J. Warner and Reginald H. Giles, of New York City; Lewis B. Grant, Charles M. Heminway and Henry A. Kentworthy, of Brooklyn.

The North Shore Gas Company, Waukegan, Ill.—to operate gas and electric plants. Capital stock, $1,000,000. Incorporators: W. I. Osborn, E. W. Bentley and M. C. Smith.

The Marietta, Williamstown and Parkersburg Electric Light & Railroad Company, Williamstown, W. Va.—to build and operate electric railway and light plants. Capital stock, $500,000. Incorporators: M. P. Goodman, W. R. Ryan, W. Weil, all of Cleveland, O.; C. M. Mayheir, J. A. Griffin, T. F. Barrett, all of Williamstown.

The Rockingham County Light & Power Company, Portsmouth, N. H.—to do a general electric business. Capital stock, $350,000. Incorporators: W. D. Lovell, Boston, Mass.; A. E. McKeel, R. N. Elwell, both or Exeter; S. W. Emery of Portsmouth and R. D. Hood of Hampton.

The A. E. Hemmel Electric Company, New York City. Capital stock, $3,000 Directors: Andrew Reich, Jr., and J. R. Simpson, New York City; G. Bayard Miller, Brooklyn.

The Grimes Creek Electric Power Company, Camden, N. J.—to supply electricity. Capital stock, $100,000. Incorporators: H. Hoopes, T. G. Janney and W. F. Eidell.

The National Gas Governor Company, San Francisco, Cal.—to deal in gas and electric meters. Capital stock, $100,000. Incorporators: G. R. Kibbe, M. E. Kibbe, H. R. McDougall, all of San Francisco; B. F. Ellis, E. F. Ellis, both of Berkeley.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 6, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

661,077. Street-Car Turn-Table. Otto G. Rieske, Dayton, O., assignor, by mesne assignments, to Ernest B. Schneider, Zanesville, O. Filed July 22, 1899.

661,448. Electric Traction of Trains of Vehicles Upon Rails. Lucien Genty, Marseilles, France. Filed May 3, 1900.

661,458. Current-Distributer for Electric Railways. Heinrich Schramm, Nuremberg, Germany, assignor to Otto Herrmann, New York City. Filed May 9, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

661,107. Carbon Pencil or Electrode for Electric Lights. John F. Saunders, Chicago, Ill., assignor to Harry Brown, same place. Filed Sept. 25, 1899.

661,125-661,126. Electric-Arc Lamp. John A. Heany, Philadelphia, Pa., assignor to the Teter-Heany Developing Company, same place and Charleston, W. Va. Filed Feb. 27, 1900.

661,456. Electric Candlestick. Lawrence F. Lewis, New York City, assignor of one-half to Charles G. Till, same place. Filed Jan. 25, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

661,127. Electrical Measuring Instrument. Fredrick A. La Roche, New York City. Filed Aug. 22, 1900.

661,195. Automatic Magnetic Circuit Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company of New Jersey. Filed July 22, 1899.

661,196. Rheostat and Circuit Breaker. William M. Scott. Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company of New Jersey. Filed Sept. 28, 1899.

661,292. Dynamo-Electric Machine. John F. Kelly, Pittsfield, Mass. Filed May 11, 1900.

661,306. Dynamo-Electric Machine. Cummings C. Chesney, Pittsfield, Mass. Filed May 11, 1900.

661,464. Alternating-Current Motor. Wales Aldrich and Henry E. Borger, Dayton, O., assignors to D. L. Bates & Brother, same place. Filed April 30, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

661,260. Transmitter. Richard H. Ferguson, Baltimore, Md. Filed Aug. 15, 1900.

661,465. Electrical Switch. Nathan Bassett, Philadelphia, Pa., assignor to the Globe Telephone Manufacturing Company, same place. Filed Feb. 8, 1900.

MISCELLANEOUS.

661,085. Process of Making Accumulator-Plates. Zdzislaw Stanecki, Lemberg, Austria-Hungary. Filed Nov. 9, 1899.

661,165. Protecting Underground Metallic Structures from Effects of Electrolysis. Lucien I. Blake, Lawrence, Kans. Filed Aug. 9, 1900.

661,173. Electric Call or Signal Box. George G. Glenn and William S. Sullivan, Philadelphia, Pa. Filed April 20, 1900

661,227. Commutator-Collector. Henry G. Reist and Edward L. Aiken, Schenectady, N Y., assignors to the General Electric Company of New York. Filed June 25, 1898.

661,228. Adjusting Brush-Holders. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed March 22, 1900.

661,244 Electric Cable. William M. Habirshaw, New York City. Filed Sept. 26, 1900.

661,291. Sparking Igniter for Explosive-Engines. Axel Johnson, Winchester, Mass. Filed Jan. 31, 1900.

661,335. Electromechanical Clutch. Russell E. Cryder, Chicago, Ill., assignor to Charles F. Chapman, same place. Filed March 30, 1900.

661,340. Means for Electrolyzing Liquids. Albert R. Grever, Philadelphia, Pa. Original application filed May 17, 1900. Divided and this application filed July 18, 1900.

661,385. Apparatus for Determining the Position of Foreign Bodies by Means of Roentgen Rays. Charles Remy, Paris, France. Filed Sept. 28, 1899.

THE TELEPHONE WORLD.

Cheaper 'Phones for Camden, N. J.

The recent controversy over the erection of poles by the Eastern Telephone & Telegraph Company has attracted public attention to this new local competitor of the Bell Telephone service. It has also served to disclose some of the methods by which the Bell interests, which have monopolized the local field ever since telephones were first introduced, are trying to cripple the competitor and prevent competition.

The Bell Company, in its monopoly of the business, had the public absolutely at its mercy for many years, and until the expiration of certain valuable telephone patents had no competitor. The public groaned under exorbitant rates coupled with poor service, but there was no hope of relief until the way was opened for competition.

In Camden, as in Philadelphia and other great centers of trade, complaints against the telephone monopoly have been heard for years, but whenever a competing company tried to enter the field the old company managed, by hook or crook, to keep them out, and thus was able to maintain its high rates and ignore the public demand for a better and cheaper service.

This was not a difficult task because the would-be competitors were mostly speculative concerns managed by men from outside the town, who had no vested interests in Camden, and who were mere franchise-getters. The reverse was the case when the Eastern Telephone & Telegraph Company was formed, within the past six months, for the purpose of filling the long-felt want of a cheaper and better telephone service.

The new company is controlled absolutely by Camden men and is backed by local capital. It has over a hundred stockholders, including some of the leading business men of the town who, appreciating the need of telephone competition, were glad to aid in a practical movement to that end. The men who put their money into the new company have the best interests of Camden at heart, representing as they do financial and business interests that are dependent upon the prosperity of the town.

The new telephone service will be in operation by February 1, 1901.

Some time ago the people of Birchwood, Tenn., and surrounding section decided that they would like to have telephonic communication with the outside world. The East Tennessee Telephone Company had a line extending from Athens over to Decatur in that State, but there was no line running along the bank of the Tennessee River, where it was most needed by farmers to keep in touch with the markets. B. L. Tolley, merchant and farmer of Birchwood, accordingly organized the Tennessee River Telephone Company, which elected Mr. Tolley president. The company decided to build its own line, and made arrangements with the East Tennessee Company to connect with the latter's line both at Chattanooga and at Decatur. The line is now in course of construction and has been finished north to Decatur. T. J. Tolley has the contract to construct the line to Chattanooga. The line runs nearly parallel with the river, and boxes have been placed in farm houses all along the line. Enough money was paid in by the farmers at the start to pay the cost of building the line, and after its completion they expect to maintain it by such small fees and rents as will be collected from those using the line.

At a recent meeting of the Mattoon, Ill., Telephone Company, officers were elected as follows: President, I. A. Lumpkin; vice-president, C. E. Wilson; secretary and manager, John W. Gay; treasurer, W. C. Lumpkin; new members of the board of directors: J. W. Bledsoe and C. E. Wilson. The company has found it necessary to enlarge the switchboard, so as to accommodate 600 instruments.

A novel independent home telephone company has been organized, composed of twelve men, merchants and farmers, to construct a line of twelve miles, from Stearleyville to Bowling Green by way of Poland, Ind., each of whom is to build and equip one mile, each member to put in his own instrument and make his own connections.

The National Telephone Company of Wheeling, W. Va., having acquired a franchise from the county commissioners, will at once proceed to extend its lines out the Pike to Elm Grove and Triadelphia, W. Va., and intermediate points, and later will extend to West Alexander and Little Washington to a connection with a line from Pittsburg.

The Citizens' Telephone Company of Houston, Tex., recently filed an amendment to its charter in the Secretary of State's department, increasing its capital stock from $200,000 to $300,000.

The Telephone, Telegraph & Cable Company has begun work on a new line through White Plains, N. Y.

The Sea Cliff Telephone War.

The New York & New Jersey Telephone Company and the South Side Telephone Company of Long Island are both reaching out after the telephone patronage at Sea Cliff, N. Y., and there is rivalry of the bitterest kind between them. The New York & New Jersey has the prior right, but is at a disadvantage by not having a regularly granted franchise. The South Side has a franchise granted by the village board of trustees, but is experiencing a difficulty in getting a foothold. The older company can not place poles in the village, but it can and does use the poles of the Franklin Electric Illuminating Company, and by so doing goes anywhere it wishes to go. The Franklin Company has recently put in a number of new poles, and the South Side Telephone Company evidently inclines to the belief that the poles are really intended for the use of its rival, while ostensibly belonging to the Franklin people. With this grievance to state, the South Side Company's representative went before a special meeting of the Sea Cliff village board a short time ago. Representatives of the New York & New Jersey Company were also present, and an interesting time ensued. The endeavor to find out to whom the new poles really belonged resulted in a statement conflicting with one recently made before the board, and the question became so complicated in discussion that it was deemed necessary to refer the matter to the corporation counsel for an opinion. The South Side Company's franchise gives the privilege of erecting poles and stringing wires, subject to the approval of the village officials, and will not permit the placing of any pole in front of a piece of property without the consent of the property owner. The Franklin people's franchise apparently permits them to place poles wherever needed, and this gives the New York & New Jersey people a decided advantage, under present conditions. The latter company has for a long term of years had a monopoly of the telephone business in Sea Cliff, and is naturally anxious to do everything possible to keep the rivals out. The South Side Company, however, has received so much encouragement from the officials, the business people and residents generally that they are determined to make the most of their franchise, and get a strong foothold.

General Superintendent James F. Land of the Michigan Telephone Company, announces that there will be practically only one telephone system in Detroit by January 1, 1901. There are now about 1,400 people who use the Detroit telephone system, but when the Michigan Company's new switchboard is in commission, which will be by January 1, users of the Detroit Company's 'phones will not be able to connect with the Michigan Company's 'phones, as the Michigan Company's new switchboard will be one of a battery system, while the Detroit Company's switchboard is of the magnetic system, and the two will not work together.

The Oakland Telephone Company lately placed some of its wires on the poles of the Michigan Company in Pontiac, Mich., with the understanding that it could do so by paying a rental. The Michigan looked at it otherwise and cut the rival company's wires. The town has now given the new company privilege to put up a line of poles of its own.

A Citizens' Telephone Company, solely for convenience and not profit, was organized recently at Adams, Tenn. J. E. Winters was elected president, W. D. Sugg business manager, and Will Edwards secretary and treasurer. The line will extend probably five miles north and south of Adams at present.

The Citizens' Telephone Company of Shelbyville, Tenn., organized a short time ago by the election of John D. Hutton, president; S. J. McCrew, vice-president; R. P. Shapard, secretary, and J. B. Frierson, treasurer. It is understood that the company will begin operations at once.

According to news received from St. Petersburg the telephone systems of the Russian cities, hitherto operated by the State, will be sold at auction on November 20. It is understood that the St Petersburg Municipal Government will bid for the local franchise.

It now seems quite probable that a telephone line between Savannah, Tenn., and Florence, Ala., will be put in in a short time. This will add another important connection with the outside world.

A boycott inaugurated by druggists, grocers, butchers and other retail merchants in Charlotte, N. C., against the Bell Telephone Company has gone into effect. The trouble arose over an increase of rates.

The citizens of Grange, N. H., have petitioned the New England Telephone Company to extend its lines to that place.

A new telephone company has been organized in Lehighton, Pa., to be known as the Lehighton Telephone Company. Messrs. A. P. Herlin, George Coffin and Pearl Prutzman, of Slatington, and A. F. Diefendorfer and others of Lehighton are at the head of it. A charter of incorporation has been applied for and at the next meeting of the council application will be made for the right of way to do business in the borough The new company is to succeed one that is in operation at Slatington and in most of the towns of Monroe County. It is the intention to connect Lehighton with the various towns in Monroe County and Slatington.

The new line of the Inter-State Telephone Company from Raleigh to Wake Forest, N. C., is almost completed. This means another telephone connection with Virginia, for from Henderson there is a branch line to Clarksville, Va., which in turn is connected with all of the important stations in Virginia. Raleigh is now on speaking terms with New York City, by way of Greensboro and Danville, and so on following the railway line to New York. There is also good connection with all of eastern North Carolina, including Wilson, Fayetteville, Dunn, Smithfield, Wilmington and all eastern towns.

The first number of the "American Telephone Journal," a weekly telephone paper will make its appearance on November 15. It is a combination of the "Weekly Telephone Items," published by Frank A. Burrelle, and general telephone news and articles. The present editor and proprietor, W. H. McDonough, who is a thorough business man, will no doubt make of the new enterprise a decided success. The offices of the paper are at 120 Liberty street, N. Y., and the subscription price $3 a year.

The Citizens' Telephone Company has applied for and received a franchise to operate a telephone system in Xenia, O. Marcus Shoup and a number of Chicago capitalists are at the head of the movement and expect to begin work shortly. They will furnish a $1,000 bond for the completion of the line and will give the city six telephones free. The system is an entirely new one, and is much better than the old. The price of telephones will be $1 in residences, $2 in business houses and $3 for both.

The Automatic Telephone Company put its first batch of telephones into commission in New Bedford, Mass., recently, about 100 in number. These are open for business and others will be put in soon. The instruments are being installed at the rate of about 20 per day, and about 600 in all are what the company will start with.

Manager Burk of the local telephone company of Binghamton, N. Y., announced recently that members of the construction company, which will build the plant there, will commence work immediately. Poles have been secured for all of the various routes and all that is awaited now is the wire and other material needed for the system.

The Cumberland Telephone & Telegraph Company has announced new rates to all county towns ranging from 10 to 20 cents, which is greatly appreciated by patrons at Dayton, Tenn.

The telephone system in the New York & Queens County Railway Company's building, Long Island City, was destroyed by fire last week.

The Texas Telephone Company of Brenham lately filed an amendment to its charter increasing its capital stock from $5,000 to $10,000.

Judge B. M. Critchfield, of Sunbury, O., is contemplating the construction of a telephone exchange at Johnstown, Licking County, O.

The Citizens' Telephone Company of Morristown, Tenn., recently purchased the exchange at White Pine, Tenn.

The United States Telephone Company of Cleveland, O., has increased its capital stock to $2,000,000.

TELEPHONE INCORPORATIONS.

The Norwalk & Huron County Telephone Company, Norwalk O. Capital stock, $80,000.

The Amherst Home Telephone Company, North Amherst, O. Capital stock, $25,000.

The Caldwell Independent Telephone Company, Caldwell, O. Capital stock, $5,000. Incorporators: W. H. Bowran, F. M. Martin, John Emmons, Joe H. Ryan and David Friedman.

The Illinois Telephone Construction Company, Chicago, Ill. Capital stock, $2,500. Incorporators: Henry Shafer, S. W. Moon and Frank L. Bills.

GENERAL ELECTRICAL NEWS.

Lighting.

Alexandria. Va.—The Southern Railroad Company of this city is making arrangements for the erection of an electric plant on its premises for the purpose of lighting the offices, shops and yards.

Bessemer, Ala.—T. T. Huey of this city wants an approximate cost of an electric light plant for a city of 10,000 inhabitants.

Blue Mound, Ill.—This place is making preparations to build a new electric light plant.

Brownsburg, Ind.—Plans are being formulated to build an electric light plant at this place.

Cottage Grove, Ore.—The electric plant owned by A. Nelson was recently destroyed by fire.

Easton, Pa.—The organization of the new electric light company for this town is proceeding. The people who are back of the venture mean business.

Florence, Ala.—The Florence Gas Light & Fuel Company will ask the city council for a franchise for an electric light plant to be operated in connection with its gas plant.

Georgetown Ky.—This city will vote on an issuance of bonds for constructing an electric light plant. A. H. Sinclair, mayor.

Greenport, N. Y.—Public ownership of the electric light and water franchises, which was an experiment in this village prior to May this year, has become thoroughly practical.

Hennessey, Okla.—The citizens of this place are agitating the question of erecting an electric light plant.

Houston, Tex.—The plant of the Citizens' Electric Light & Power Company of this city will shortly undergo considerable improvement. An order was issued by Judge D. E. Bryant authorizing the receiver of the company to purchase $60,000 worth of equipment.

Kingfisher, Okla.—This city has voted the sum of $26,000 for the purpose of putting in an electric light plant, etc.

Larue, O.—It is stated that the Larue Telephone Company will erect an electric light plant in the near future, furnishing a better light to the town than it now possesses.

Leesburg, Va.—J. W. Wright, mayor of this city, will receive bids until November 19 for lighting the streets either by electricity or gasolene for one year beginning January 1, 1901.

Linton, Ind.—An electric light plant will be installed in this city.

Madison, Neb.—The contract for erecting and establishing an electric light plant has been let to the J. J. Bennet Power & Lighting Company of Hastings.

Moline, Ill.—The council is considering the question of erecting an electric light plant at the waterworks.

Mt. Carroll, Ill.—Landlord Beaver of Hotel Glen View is figuring on putting in a water motor and a dynamo and furnishing his own electric lights.

New York City.—Sealed proposals will be received by the committee on buildings of the board of education of this city at the hall of the board, southwest corner of Park avenue and 59th street, November 19 for installing apparatus and an electric lighting plant in a new public school in the Borough of Brooklyn.

Port Jefferson, N. Y.—The question of establishing a lighting district is being agitated and a petition will soon be prepared and presented to the town board asking that body to act in the matter.

Portland, Ore.—Bids for lighting this city will be received at the office of the auditor until November 20. Address T. C. Devlin, clerk.

Rawlins, Wyo.—The Rawlins Electric Light plant will be enlarged and the capacity doubled. The improvement will cost $5,000.

Roachdale, Ind.—A. F. Fields is interested in a company that is being formed here to put in a new electric light plant.

Sardinia, O.—G. A. Kennedy is preparing to erect an electric light plant in this place.

St. Paul, Minn.—The board of public works favor the erection and equipment of a municipal lighting plant for this city.

Sayville, N. Y.—Plans are being formulated for the lighting of the streets of this place with electricity.

Tampa, Fla.—This city will vote upon an issuance of bonds for a municipal electric light plant to be secured either by purchase or construction. Address J. A. Weller, city auditor.

Topeka, Kan.—A resolution was lately adopted by the council instructing the city clerk to advertise for bids for the addition to the city electric light plant.

Weston, Ore.—This place is to have an electric light plant.

Winchester, Tenn.—McDowell & Sons of this city want bids on an electric light plant.

Street Railways.

Ann Arbor, Mich.—Hawkes & Angus, the promoters of the Jackson-Ann Arbor Electric Line are preparing to erect the new line.

Chattanooga, Tenn.—A deal was recently made by which the Rapid Transit Company of this city, backed by Philadelphia capitalists, has obtained possession of the Crass properties on Lookout Mountain, including the incline railroad from St. Elmo to the top of the mountain and the electric lines on the mountain.

Cincinnati, O.—A new electric railroad will be built between this city and Piqua, O., and will be known as the Troy, Tippecanoe & Dayton Interurban Railway. E. H. McKnight, P. Schwab and Col. F. Foster will be the owners of the new road.

Dayton, O.—The Dayton, Springfield & Urbana Electric Railway Company was recently incorporated by F. Colburn, J. G. Webb, J. S. Harshman and W. H. Hanford.

Elwood, Ind.—H. Stillwell is at the head of the new electric railway to connect this city and Indianapolis by way of Tipton.

Ft. Wayne, Ind.—A. N. Dukes of Peru is the promoter of the Towpath Electric Line from this city to Lafayette through Logansport.

Grand Rapids, Mich.—Plans are completed for the building of an interurban electric road from this city to Belding. The road will go by way of Mill Creek and Grattan. G. Stewart Johnson of the Grand Rapids Street Railway Company is one of the parties interested.

Huntsville, Ala.—An electric railway is projected from this city to the Tennessee River. The company that will build the line will be known as the Coatesville & Whitesburg Electric Railway Company.

Ithaca, N. Y.—It is probable that an electric line will be built between Auburn and this city.

Junction City, Kan.—The Junction City Electric Railway, Light & Ice Company has been incorporated with $100,000. The company intends to construct an electric railway from this city to Fort Riley and also operate an electric light plant. The directors are S. W. Pierce, W. W. Cook, J. K. Wright, F. E. Tyler, C. K. Raber and J. Humphrey.

Lima, O.—The Columbus, Lima & Northwestern Railway Company has been organized with $10,000 capital stock for the purpose of operating an electric railroad through Allen, Auglaize, Hardin, Logan, Union, Delaware and other counties. The incorporators are J. C. Brand, E. W. Hamilton and W. E. Sheridan. The principal office is to be in this city.

Meadville, Pa.—It is said that the Meadville Traction Company intends to build an electric line from here to Cambridge Springs, and there connect with the line running to Erie. The distance from Meadville to Erie is 40 miles.

Otsego, N. Y.—This town has granted a franchise to the Oneonta, Cooperstown & Richfield Springs Electric Railroad.

Philadelphia, Pa.—Sir William C. Van Horne is at the head of a company recently formed with a capital of $20,000,000 to develop important railroad and other interests, also to secure control of electric light and trolley franchises in Cuba and to establish plants and systems in every city.

St. Louis, Mo.—The St. Louis, Clayton & St. Charles Railway Company lately petitioned the St. Louis County Court at Clayton for franchises for the construction of three new electric lines in St. Louis County.

Syracuse, N. Y.—The Syracuse & Oneida Lake Electric Railway Company has broken ground for its proposed trolley line between this city and South Bay on Oneida Lake.

Weyauwega, Wis.—W. C. Lawrence and C. C. Pierce of Chicago, A. L. Hutchinson, W. H. Weed and E. H. Jones of this city, are interested in a corporation about to be formed and known as the Wisconsin Midland Railway Company. The present capital stock is $25,000. The object is to build an electric railway line from Berlin to New London via this city and from Poy Sippi to Wautoma via Pine River.

Manufacturing.

Concord, N. H.—A new manufacturing company has located in this city, and is at present actively engaged in the manufacture of an electrical instrument, which is so designed and constructed that it can be attached to one or more generators or dynamos, and will hold the voltage constant at any desired figure from full load to no load taking care of all fluctuations caused by motors and uneven power.

Washington, D. C.—S. D. Newcomb, D. H. Zeigler, D. Messick, C. N. Wine and A. P. Marsh, all of this city, are interested in a recently organized concern known as the Eastern Electric Manufacturing Company, which will manufacture and sell electrical goods on a capital of $1,000,000.

Company Matters.

Hartford, Conn.—The Hartford Electric Light Company has filed in the State Secretary's office a certificate of increase of capital from $700,000 to $1,050,000.

New York City.—The Queens Borough Electric Light & Power Company has lately filed a certificate of increase of capital stock from $250,000 to $410,000.

Norfolk, Va.—The Southern Electrical Equipment Company was recently placed in the hands of a trustee in this city. The liabilities are $7,000.

Sandusky, O.—Business of the Warren Electric Company is very heavy this fall, and the plant is running full time. Mr. C. C. Warren says: "We have orders enough on hand now to more than run us the balance of the winter."

Yarmouth, Me.—All of the machinery, tools and electrical appliances of the Taber & Mayer Company of this place were sold at auction a short time ago to the Yarmouth Manufacturing Company. The plant was established several years ago for the manufacture of telephones for short lines.

Power and Transmission.

Telluride, Col.—On the new plant of the Telluride Power Transmission Company, at Vance, work is going rapidly ahead and the management expects to be ready to furnish power by December 1.

Automobiles.

Chicago, Ill.—The Auto Appliance Company with a capital of $50,000 has been formed here by E. M. Winston, K. J. Green and Ira B. Hutchinson.

Cumberland, Md.—The Maryland Automobile Manufacturing Company of Western Port, whose office is in this city, is negotiating for the purchase or lease of the plant of the Piedmont Foundry and Machine Shops, at Luke, owned by the Twin-Towns Manufacturing Company and operated by Mr. Robert Smith. Mr. Smith is arranging to erect a shop and foundry of his own.

Middletown, Conn.—P. H. Flynn, who is interested in the New York Vehicle Company, which has secured from the trustees of the Worcester Cycle Company two brick factory buildings in this city, recently said: "The buildings were bought for use as an automobile plant, and we will improve the plant. It is expected that between 200 and 300 men will be employed, and that the pay roll will amount to about $60,000 a month."

Newark, N. J.—A branch of the New Jersey Automobile Company has been organized here with its office at 788 Broad street. This concern will do business in Hudson, Essex and Bergen Counties. Arthur H. Hayes, George Paddock and Frederick E. Hodge are among those interested.

Raymond, Cal.—Negotiations are now pending for the supplanting of the present stage line from here into the Yosemite Valley by a line of automobiles.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The Welsbach Company is said to be earning 6 per cent on its stock.

R. G. Dun, head of the R. G. Dun Mercantile Agency, died on the 10th inst.

The character of buying in Electric Storage Battery common seems to verify the predictions that the price will cross 100 before the end of the present year.

Philadelphia Electric gold 5s, which on Saturday advanced 1¼ points to 101¼, will, it is predicted, soon cross 105; the 4 percent. bonds are in active demand at 69.

The City and Suburban Telegraph Company of Cincinnati recently certified to the Ohio Secretary of State an increase in its capital stock from $2,500,000 to $4,000,000.

A trust mortgage for $1,500,000 has been filed by the Grand Rapids, Holland & Lake Michigan Rapid Railway Company to the American Trust and Savings Company in Detroit, to secure $1,500,000 worth of bonds.

The American Bell Telephone Company reports the output of instruments for the month ended October 20 as follows: gross output, 67,198, increase, 16,337; returned, 30,737, increase 12,693; net output, 36,461, increase, 3,644.

Brooklyn and New York traction securities have been the most active and strongest portions of the New York Stock Exchange list in the bull market which has so suddenly developed. In this movement of the stocks in question there is plenty of evidence that manipulation has had a leading share.

Judge Coxe of the U. S. Circuit Court, New York, in the case of the Electric Vehicle Company and George B. Sheldon vs. Winton Motor Carriage Company upholds the so-called "Sheldon" patents. If the decision is upheld it means that the owner of the patents—the Electric Vehicle Company—has a virtual monopoly to manufacture and use automobiles of the gas and oil type.

There has been renewed interest in Massachusetts Electric Companies' securities by reason of the recent favorable decisions by the Railroad commissioners. The company is fast consolidating its properties. The annual report it is said will make a very favorable showing. Over $1,000,000 has been expended for betterments during the year and the report will show earnings of between 2 and 3 per cent. on the common stock.

The executive committee of the American Telephone and Telegraph Company, consisting of President Alexander Cochrane, Charles W. Amory, and Henry S. Howe, will arrive in St. Louis in a few days to inspect the telephone property in that city. En route to St. Louis the committee will visit several large cities. St. Louis is probably selected as one of the points of inspection from the fact that the largest independent telephone company is in operation there.

At the annual meeting of the stockholders of the Jersey City, Hoboken and Paterson Street Railway Company, held in the offices in Hoboken, the information was given out that the earnings of the combined roads, under the management of President David Young, had greatly exceeded the expenses during the past year. The total earnings of the combined roads, over and above the operating expenses and the amount required to pay interest on the bonds, reached $100,000.

A number of New York. Philadelphia and Canadian capitalists sailed from Philadelphia on the 9th inst. in the interests of the Cuba Company, which was organized some time since with a capital of $20,000,000. Sir William C. Van Horne, chairman of the board of directors of the Canadian Pacific Railroad, was in the party. The purpose of the Company is to secure control of all electric light and trolley franchises in Cuba and to establish plants and systems in every city.

No confirmation can be obtained at the New York office of the General Electric Company of the report that the company was among the bidders on a $25,000,000 contract soon to be awarded by the London, Metropolitan and District Underground Railway Company for the equipment of its system with electricity. It was said, however, that the British Thomson-Houston Company, the European connection of the General Electric Company, might be figuring on the contract.

The plan to build a railroad between Washington and Gettysburg has assumed such shape that George T. Harries, president of the Washington & Gettysburg Railroad Company, says that the preliminaries for its construction have practically been completed. The road will be 72 miles long and will extend from Washington through central and western Maryland. It is understood that the company represents interests which have large holdings in the street railway system of Washington.

Messrs D. Houston & Co., metal brokers, New York, in their monthly market letter say: "The continued large demand for lake copper has been a feature of the situation, which would seem to indicate the manufacture of a great deal of brass even though the Brass Association was dissolved October 1. Consumers are not carrying the customary stocks of ordinary times, and must therefore enter the market for new supplies on a generous scale at no very distant date. With so many producers well sold up for the balance of the year, the quantity of available copper supply is more concentrated and there are no weak holdings apparent anywhere.

The earnings of the Chicago Union Traction Company in the month of October were $45,997 less than earnings in the corresponding month last year. The total for the month was $633,043, which is also less by $7,000 than the earnings in the month of September. These figures do not come directly from officers of the company but are reported authentic. The officers recently decided not to continue publication of the monthly returns of earnings. The decrease in October makes the total decrease for the four months of the present fiscal year since July 1 $50,362. July showed a decrease of $22,000 on top of a still heavier decrease in June, but August and September showed increases in the figures.

EDITORIAL NOTES.

The Abuse of the Word Electrical.

Ever since electricity was turned to practical use in the industries enterprising persons with more brains than scruples have made use of the word electricity, or a derivation of it, to further some wildcat scheme and interest, financially, that class of people who are reputed to be born every minute.

Innumerable fakes in the way of electric belts have appeared from time to time in the market. The Rev. Dr. Jernegan, it will be recalled, took a trip to Europe some two years ago with well-filled pockets containing the proceeds of a cleverly gotten up scheme for extracting electrolytically gold from sea-water, but which only succeeded in extracting gold from credulous New Englanders, while now we hear of another enterprise in which again the word electro is brought in, presumably because unsophisticated people are readily made to believe that electricity is omnipotent. We refer to the so-called Electro-Pneumatic Transit Company, which the New York "Herald" has been investigating in the interest of the investing public. After referring to several cleverly worded advertisements, which this company has had inserted in a number of the daily papers regarding the value of its stock, the "Herald" says:

"Stock of an electro-pneumatic company has undoubtedly been quoted on the Wall Street 'curb' for upward of three years. Sometimes it has been sold and sometimes it has been 'washed up,' and at all times there has been a veil of mystery covering the actual or supposititious transactions. It may be added that a veil of mystery also covers the company from its inception to the present day.

"Nearly every company which appeals for public support through Wall Street has a charter, real or fancied officers and offices for the transference of stock, and numerous other things, besides certificates of stock that lead to a belief in its actual existence. The Electro-Pneumatic Company is, of course, similarly situated so far as a revived charter is concerned. Yet so little is known of it that a search recently in the City Directory of 1900, the investors' supplement of the 'Commercial and Financial Chronicle,' the Manual of Statistics of 1900 and the Corporation Directory of 1900 failed utterly to disclose such a company, the names of the officers thereof or any details concerning the organization, amount of capital stock, financial statement or anything else that a company usually provides when it appeals to the public for support.

"Some developments have recently taken place in the Electro-Pneumatic Company, but so far as a diligent investigation has been revealed there has been no actual change in the nature of the enterprise since April 8, 1900, when Cuthbert Mills, a well-known financial writer, published the following in his article in the New York 'Tribune':

"Just about a year ago a single line appeared in this column in respect to a stock in the 'outside market' entitled Electro-Pneumatic, and quoted at 5 or 6. That unfortunate line baited a hook which apparently caught many fish, judging by the letters received when Electro-Pneumatic disappeared from the quotation list. It is now being industriously washed into view again. Its value is the paper it is written on."

Continuing the paper quoted above says:

"Almost the first statement in the advertisement is misleading. It is as follows: 'Electro-Pneumatic Transit stock, now selling under $4 per share, represents intrinsic value which till now has been repressed by reason of circumstances whose removal makes great accomplishments possible.'

"There is no 'intrinsic value' to the stock. It may have a value in the future, but that is contingent, not intrinsic. The 'repression' in value, so termed, is due to the fact that the company lost its charter. In some way it is said to have reclaimed a charter, but whether such reclamation carries with it any rights under the old charter and patents is a matter which will have to be threshed out in the courts.

"What investor wants to buy a participation in a costly law suit? Such is the condition that confronts any purchaser of Electro-Pneumatic stock, for if it has any merit above what Mr. Cuthbert Mills says is 'the paper it is written on' such value is contingent upon the future adjudication of its titles by the courts.

"When men make appeals to the public to buy stock, it is customary to give some details of the proposition. Not one, however, appears in connection with the Electro-Pneumatic Transit advertisement.

"Presuming that it really has an incontestable charter, where are the names of its president, its officers and directors? Where are

Digitized by Google

stated the amount of its capital stock and the par value of the shares? Where are its annual report and balance sheet? Where is its plant? What are its patents, held with a free and clear title? And what plant has it installed with the exception of a short strip of tube in Philadelphia, put in by a company, the relations of which to the Electro-Pneumatic Company are now in dispute?

"The advertisement, however, unqualifiedly recommends the purchase of the shares of this company, and by a clever juxtaposition of phrases, mentions it in connection with 'gas company stocks and bonds, gilt-edged issues of New York ferry corporations and the street railway stocks of the country,' and along with the Amalgamated Copper Company, the Standard Oil Company and the New York Air Brake Company, to which it is directly compared.

"References, by the way, to these companies are simply because Electro-Pneumatic is sold on the curb as are other securities mentioned, but no mention is made at the same time of certain other curb securities, Union Copper for instance, or Gold Hill Copper, Bay State Gas, or Electric Brake and Coupler, and there are other securities on the curb which are not as good as Standard Oil and never will be."

It is to be regretted that almost invariably whenever a "wildcat" scheme is thought of the promoters deem it necessary to attach a word to the title that leads people to infer that it is in some way electrical, for by so doing a slur is cast upon other legitimate electrical securities.

* * *

Electric Vehicle Trials in England.

In view of the large amount of interest now being taken in automobiles in this city, due in a great measure to the automobile shows, the following regarding the popularity of electric vehicles in England, and for which we are in part indebted to our London correspondent, should prove interesting.

That the electrically propelled automobile has not made much headway in England is fully demonstrated in the poor number of entries for the competitive trial runs which commenced there on November 6th. The Automobile Club was desirous that electrical vehicles should have every possible encouragement, and it accordingly arranged a series of trials for three consecutive days, at the same time appointing a judges' committee made up as follows: Professor Vernon Boys, Professor C. A. Carus Wilson, Mr. Hugh Harrison, Major H. C. L. Holden, F.R.S., Sir W. H. Preece, Sir David Salomons, Mr. James Swinburne and Mr. Alex. P. Trotter.

The arrangements for the runs were that vehicles should traverse a given course on one charge on Tuesday, November 6th. The following day there was a run of 30 miles, including considerable gradients, and on Thursday 30 miles of average road. The batteries were charged at the Chislehurst Electricity Works each night, and before arriving there they were discharged to 1.8 volts per cell, the owners' representative deciding when they were fully charged. Each day's run was within 50 miles of London, but the exact district was not known to competitors until just before the runs. There were six entries and one had to be withdrawn for unavoidable reasons; there were, therefore, five, as follows:

One Joel car to carry two persons, with Rosenthall battery and Joel motor. Entered by the National Motor Carriage Syndicate of London.

One car, four persons, electro motive power Coy's batteries and two pole motor.

One car ditto, but with four pole enclosed series motor.

One Still Motor Company's car, four persons, "Ideal" battery and Still motor. Entered by the Canadian Electric Motor Company of London.

One car for three or four persons with Leitner battery and Lundell motor. Entered by Electrical Undertakings, Ltd., of London.

The finding of the committee has as yet not been made public.

* * *

The Value of a Trade Paper.

Very few persons connected with the electrical industry, either in the capacity of manufacturer or retailer, can realize what an amount of thought and expense is lavished upon their particular trade paper. They get it week after week, look it over critically for the many interesting items and articles which it contains, many of which they could not possibly get through any other source, carefully scan the advertising pages for any thing which is offered for sale, either new or old, and then lay it away with never a passing thought for the ways and means that allow for this.

To produce a trade paper which does not belie its name means the expenditure of much thought and care; the news must be strictly up-to-date, otherwise it will be useless.

One has only to look at the trade paper of a few years ago and compare it with one of the present day in order to note the strides which have been made toward perfection. Every topic upon which full and reliable information is essential to buyer and seller is treated in detail, and to make it of any value whatever means a careful revision that is entirely foreign to the ordinary run of publications.

Looked at from a mechanical standpoint, the high-class trade paper is a thing of beauty. Being usually of a generous size and printed on fine paper, the highest efforts of the printer's are possible, and its contents are therefore made pleasing alike to the eye and mind, and all this costs money. Several of the American trade journals have, as such, no superiors in the world, either in regard to the scope and value of the information furnished to the branches of the industry they represent, or the commanding position they have attained in class journalism. And it may be safely asserted that no business of any importance could be carried on to-day without an organ devoted to its interests.

There are comparatively few instances where any number of a paper like Electricity fully completes its mission of usefulness. It is read by the head of the house receiving it, perhaps by two or three of his business associates, occasionally by some of the office men, and then is too often filed away or taken possession of by some individual.

The fact of the matter is that the trade paper should have a wider circulation within the personnel of any business than is usually the case. There is hardly an employe in the electrical and kindred industries who would not be of more value to his employer if he were a regular reader of Electricity. If he lacks sufficient interest to subscribe for himself or if he feels unable to do so it would, in most instances, be a profitable investment for his employer to subscribe in his behalf. In any event a copy of the paper should be where the leading employes could find it and they should be invited to avail themselves of that privilege. They should be urged to do so, for within his narrow limitations any salesman or shipping-clerk can secure relatively as much benefit from the columns of a reliable and progressive trade paper as his principals.

Too many salesmen and clerks of proficiency fail to bring the best results to their employers simply because they are confined in too narrow a groove and are not given the opportunity to take that outlook into the world which broadens the mind and quickens the perceptions. Electricity is not designed especially for the employe, but it is to be hoped that there will never be an issue of the paper in which everyone connected with the industries it represents, even though it be in an humble capacity, may not find something to his profit. Even if that something be not directly in line with his particular work it is well for the ambitious, and, therefore, useful employe, to know in what relationship his particular line of work stands to the completed result: what it is that lies outside and yet within reach of him in other departments of the business.

Reading a paper like Electricity should make every salesman, artisan and clerk better fitted for his work, and, therefore, more profitable to his employer.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A press dispatch from Seattle, Wash., November 17, says the Snoqualmie Falls Power Company of that city performed a novel feat in the driving of an electric motor 153 miles distant from the generator. All the transmission lines of the company were connected in one continuous circuit, commencing at Snoqualmie Falls, running to Seattle, back to the falls, then to Tacoma and back again to the falls. The regular transmission is thirty-two miles to Seattle and forty-four miles to Tacoma. The tests were conducted for experimental purposes only and to show that electric transmission of power can be made commercially practicable at much greater distances than has heretofore been contemplated.

At Sault Ste. Marie, Ont., another great center of electro-chemical industry is springing up. A company has been organized, with a capital of $30,000,000, to develop the water power on both the Canadian and United States sides. On the Canadian side, 14,000 horse-power is now being used, while 10,000 horse-power will be taken by the American Alkali Works; other industries, such as nickel reduction works and chemical works, are contemplated.

Consul Listoe, at Rotterdam, in a report to the State Department at Washington, D. C., says that a third telegraphic cable has been laid recently between the Netherlands and England, which will expedite the delivery of American cablegrams via London. One of the wires will be connected immediately with the Atlantic cables at London, thus making it possible to cable to the United States without the intervention of the London office. The cost of the construction of the cable was borne by Great Britain and the Netherlands.

The Organization Committee of the National Association of Automobile Manufacturers' of America held a meeting last week in the Hoffman House in this city and talked at length over the advisability of making the association similar in aim to that of the League of American Wheelmen and to begin a fight for better roads in this country. The Organization Committee consists of John Brisben Walker, S. T. Davis, Jr., of New York; A. L. Riker of Elizabethport, N. J.; C. J. Field of Brooklyn: J. M. Hill of New York; A. W. Winslow and E. P. Wells of Keene, N. H.

Plans for the proposed electrical workshop and storehouse for equipment to be constructed at the League Island U. S. Navy Yard at Philadelphia, Pa., are now being drawn in the Government engineering department. In the course of a month bids for the new structure will be advertised. This building will be completed in less than a year, and when formally opened will be one of the best equipped and most modern of workshops and storehouses for Government use in this country. The electrical workshop will cost about $84,000.

The Electric Boat Company of Manhattan has contracted with a firm in New Suffolk, N. Y., for a site for a basin to establish a permanent testing plant at that place. The company controls the torpedo boat Holland. A breakwater and basin will be built and half an acre of new land obtained by throwing up back of the breakwater the sand from the bay bottoms. A frame machine shop, 20 by 50 feet, and a larger engine house will be erected. It is stated that next year six boats of nearly the same pattern as the Holland will be built. Experiments will be made in Peconic Bay, N. Y.

An electric time alarm which has been patented lately has at least one novelty to recommend it. It is directly connected to the bed, and it is impossible for the sleeper to stop it until he gets up to stay. Underneath the bed is a series of contact points, the weight of the person forcing them together. A clock is used in connection with the apparatus, and as soon as the hour of rising is indicated the remaining opening or break in the wire is closed, the current passing through the contact points underneath the bed and causing the bell to ring continuously until the sleeper, by leaving the bed, breaks the circuit. Should he lie down again the circuit is again completed and the bell rings until the second rising.

The United States Consul at Magdeburg, Germany, describes an electrical farm operated in Germany in which the power for generating the electric current was derived from a stream whose waters were dammed up to secure the necessary fall to turn a large turbine wheel. Nearly all the farm machinery, including pumps, harvesters, feed cutters, threshing machines, churns and ploughs, were operated by the electricity thus generated, which was conducted to all parts of the farm on overhead wires.

Japan's navy is to have the most powerful wireless telegraph instruments ever made. These instruments, which will be sent from this city to Japan this week, were made specially for the Mikado's Government. There are two of them and they will be installed on two of the fastest Japanese cruisers. It is expected that they will be able to transmit messages at least 125 miles. The machines were constructed for the Marconi system according to Marconi principles and are in the nature of an experiment. It is now probable that the construction of much more powerful instruments will be attempted. The new instruments develop an energy of about 2,000,000 volts, the induction coils contain over one hundred and twenty-five miles of copper wire and weigh 1,500 pounds. A spark or flash 45 inches long has been drawn from them. At that distance the flash has the appearance of an undulating stream of blue fire. When the poles are set nearer together the flashes whiten until at six inches, at which distance the poles will be set when in use, the flashes resemble the flame of an arc-light. When a piece of 4-inch plate-glass was held in the track of the flash it quickly bored a hole through it as clean as an auger would make in a bit of soft wood. For each sending instrument a powerful receiving instrument has been made, which in appearance resembles those used in ordinary telegraphy. In the experiments which it proposes to make with these instruments the Japanese Government expects to accomplish results that have never before been attained with wireless telegraphy.

In the big telegraph suit to be tried at Toronto, Ont., in which the Great Northwestern, the Western Union and the Montreal Telegraph Companies are interested, the Court of Appeal was asked whether the case could not be tried immediately. Opposing counsel objected, stating that the case was one of vast importance and should come before the full court of five judges; that over $90,000,000 are invested in the disputing corporations, and that it would not be fair to the shareholders to proceed at present, as only four judges could be secured to hear the case. The court agreed, directing the case to stand over. The action was brought to attack an agreement by which the Montreal Telegraph Company was absorbed.

The semi-annual meeting of the New York State Electrical Contractors' Association was held at Syracuse, N. Y., last week. The principal business transacted was the consideration of plans for securing favorable legislation during the coming session of the Legislature. The contractors want to have the State license all electricians and a committee was appointed to lay the matter before the Legislature.

A new bottle cleaning machine that works by electricity is said to have been invented recently in Peoria., Ill.

Electric time service was first introduced more than forty years ago. In 1857, in Brussels, Belgium, what was then known as the Nolet system of electric clocks was put in service, about 100 clocks being installed at various places in the city and electrically connected with a master clock at a central point. This system, with many improvements and additions, is still working.

The Bullock Manufacturing Company of Cincinnati, O., has taken one of the largest contracts for electrical machinery that have been let for some time. The contract amounts to $100,000, and is for furnishing a complete electrical equipment for the McCloud River Electric Power Company, Shasta, Cal. The contract calls for four generators of a total capacity of 2,000 kilowatts, and the current will be transmitted 30 miles from the generating plant to the large copper mines just south of Shasta, where the power is needed for the operation of mining machinery. The plant is an unusual one from an engineering point of view, because of the distance that the current will be transmitted. The plant is located in the position that has been selected because of the water advantages, as it will be operated by water power.

In McGill University at Montreal there are thirty fourth-year students in the engineering department. Of this number eighteen, or sixty per cent., are taking the electrical course. The electrical department of the University is now taxed to its utmost capacity, and, notwithstanding the extensive improvements made in it during the past five years, the University authorities are now confronted with the problem of providing still greater accommodation, both as regards space and additional appliances.

The installation of electricity by the Manhattan Elevated Railway of this city is progressing so rapidly that it is now stated that the first train will be operated by the new power on the Second Avenue line between Fifty-ninth and Eighty-ninth street on Thursday of this week. Pending the completion of the Manhattan power-house the Metropolitan Street Railway will supply the electric energy.

The Empire State Power Company's plant at Schoharie Falls, N. Y., is now completed. The plant has cost nearly half a million dollars and is a model in every respect.

The Indianapolis "News" has completed an automobile tour of the northern part of Indiana with the view of investigating the practicability of employing automobiles in the distribution of papers to the towns throughout that State.

Mr. Thomas A. Edison has been granted a patent for a new type of electricity meter. It is said to be a very important invention and belongs particularly to the class in which chemical reactions are called into play.

The Automobile Show in the Grand Central Palace, this city, was opened on the evening of November 14. The attendance was large and persons who took the trouble to go were rewarded by the sight of an unusually large and interesting exhibition of motor vehicles of every description. The fine showing of automobiles is due to the untiring efforts of Mr. Marcus Nathan, who has also arranged for various contests and other attractive features, which will take place before the exhibition closes on November 24.

John L. French of St Louis, is the first man to make a trip from that city to Chicago in an automobile. He completed the distance of 450 miles in 36 hours, notwithstanding he encountered bad roads and frequently followed out-of-the-way directions. He made the journey to prove that the horseless carriage could be used satisfactorily on dirt roads and could be depended on to climb hills and to wheel through deep mud.

ARTICLE NO. 2.

THE LAWS OF INDUCTION.

Electricity will induce or influence magnetism.

One current of electricity will induce or influence another current.

Magnetism will induce or influence electricity.

Magnetism will induce or influence magnetism.

Surrounding a conductor over which a current of electricity is flowing there exists waves of influence circling outward and decreasing in power according to their distance from the conductor. This may be very aptly explained by the conditions noticeable when a pebble is dropped into a still pool of water; if you do this

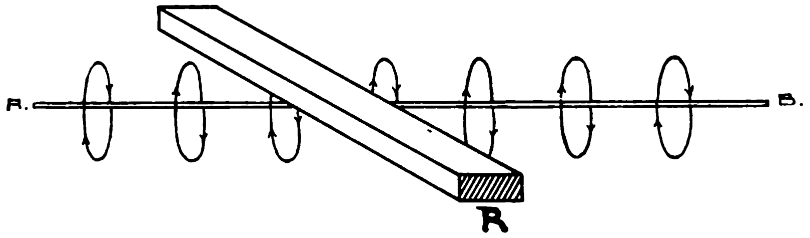

Fig. 1.

you will notice that small circling waves form and travel outward from the point where the pebble strikes. Now in just the same manner the inductive waves of force circle around a conductor through which a current is flowing. Understand and remember that this condition exists along the entire length of the conductor and remains as long as the current is applied. If a small pocket compass is held over the conductor you will find that its needle will point at right angles to the wire, then hold the compass under the wire and you will find that the needle will point in just the opposite direction that it did before, demonstrating that these force waves travel in a different direction above the wire than they do below. This proves that they must travel in a circle around the conductor, which they do, and this experiment also demonstrates that they travel in a direction entirely controlled by the direction in which the current is flowing in the circuit. These waves circle from left to right over the conductor looking in the direction the current is flowing. A good way to remember this is that these lines travel in the same direction as the hands of a watch when you are looking at the dial and the current is flowing in the direction you are looking.

For further experiments let us retain our conductor and assume that there is current continually flowing over it. Suppose we place a bar of iron at right angles across the wire, then this iron will act as a path for the waves and become magnetized. However the magnetism would be very slight and could only be detected by delicate instruments, but the more lines or waves we use this iron as a path for the stronger magnet it will become. To make a magnet then that would be of practical benefit to us we must collect a great number of these inductive waves, form a path through the iron and influence it.

Suppose, in Fig. 1, A B, represents a wire through which an electric current is flowing and the circles indicate the force waves, then the iron, R, only forms a path for the waves directly in its way, and we have the other waves playing no part nor doing nothing toward strengthening the magnetism in the iron. But suppose, as in Fig. 2, we wind the wire around the iron then you find it will form a path for all the lines for they are all bunched in the center of the circle described by the wire. Now let us see. We said these waves existed the full length of our wire, so consequently the more wire we wind around our bar of iron the denser will become the mass of lines for which the iron forms a path and it will become a stronger magnet. The strength and density of the waves depend upon the amount of current passing over the wire and the strength of the magnetism in the iron depends on the number of waves for which it forms a path. We have learned how to make a magnet by taking a piece of iron, winding a coil of wire around it and sending a current of electricity through the wire. The wire must of course be insulated, otherwise the electricity would not follow it but would take a short circuit through the mass of metal and produce no results.

To Produce Electricity by Magnetism.—If you have a wire through which a current is flowing and lay another wire parallel with it the force waves of the first will influence the second and induce a current in it provided the waves are kept in motion. Go back to our example of dropping a pebble into the water. Suppose there be a cork floating in the pool it will of course be set in motion the instant the small waves strike it. If those waves existed but remained stationary they would not influence the cork, but so long as they flow the cork is in motion. So this illustrates our induction of current in a parallel conductor. If the force waves are kept in motion then they will act upon and induce, but if allowed to remain stationary they will have no effect; so by making and breaking the circuit of the first conductor and keeping the waves in motion we induce a current into the other circuit which is parallel to it. When we start the electricity flowing, or complete the circuit, in our first wire the force waves flow from the center and

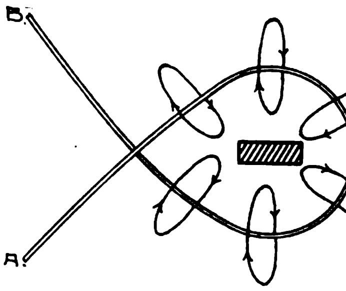

Fig. 2.

travel outward, cutting the parallel wire as they go and induce a current in a certain direction in it. When the circuit is broken these waves then flow from the outside in toward the center and cut the parallel conductor in an opposite direction than they did flowing out, and in so doing induce a current in just the opposite direction to the one first induced. This is the basis of the ordinary induction coil. We can accomplish the same result if we allow our

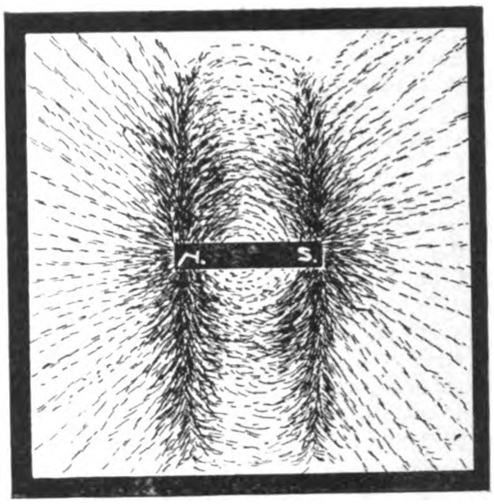

Fig. 3.

waves to remain stationary and draw the wire back and forth through them, for it is practically the same thing. This is the principle of a dynamo.

To accomplish any valuable results in this line we must have a great concentrated mass of these waves and also a large amount of wire. Iron not only becomes magnetized by the lines but it also forms a reservoir for them. If the lines could be seen surrounding a magnet they would describe a mass very much like Fig. 3. You will notice how the lines at N seem to circle toward S and the ones at S to circle toward N, with the greatest density at the two ends. If a coil of wire is put in motion within the influence of these lines of force it will have induced into it a current of electricity. The

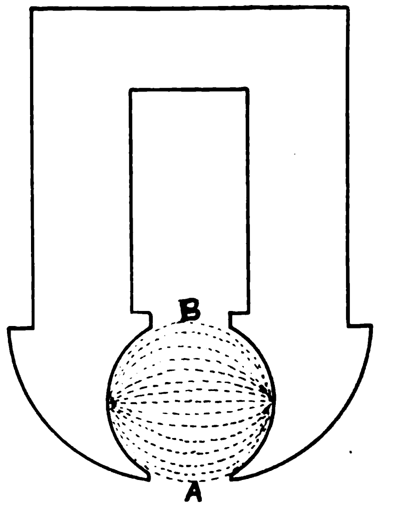

Fig. 4.

stronger the magnet the greater the number of lines and the greater the number of lines the more effect will be produced in the coil of wire.

We have seen how we can produce magnetism by electricity, how a current of electricity in a conductor will induce a current in a parallel conductor, how magnetism will produce electricity, how also magnetism will produce magnetism, for place a piece of iron against a magnet and you will find it will also become magnetized, that is, it will practically become part of the magnet itself, and the neutral point will then be where the two pieces of iron come to-

Digitized by Google

gether with the poles of the magnet as before at the extreme ends.

In a magnet the lines of force are strongest and most dense at the ends and radiate from each pole as though they were attracted by the others. This in fact is just what happens and if we use a U-shaped piece of iron for our magnet, bringing the ends closer together, we will have these lines collected into a smaller space and consequently of a much greater density, which is the object we wish to attain when we use it for inducing current into coils of wire. This gives us, as seen in Fig. 4, the shape and principle used in modern dynamos. If a closed loop of wire be passed upward from A to B between the poles the current induced in the wire will flow in the opposite direction to what it would if the loop were passed downward from B to A, demonstrating that the direction of the induced flow of current depends upon the direction the loop is cut by the lines of force.

The waves radiating from a magnet are called lines of force and the space within which they radiate is known as the field of force.

Article No. 3 will be entitled The Electrica Measurements.

THE RELATIVE ADVANTAGES OF NARROW AND STANDARD GAUGES FOR ELECTRIC ROADS.*

BY F. GUNDERLOCH.

This report considers the following question: What are the relative advantages and disadvantages of narrow gauge and standard gauge for electric street railways, especially in regard to the mounting of sufficiently heavy motors and other mechanical appliances?

On account of the greater efficiency of electric motor cars, the strictly city street car lines have been extended into suburban districts, which naturally present new problems for solution. One of these is the demand for higher speed and the accompanying necessity for heavier and stronger cars. The greatly varying traffic further made it necessary, at certain hours, to run trains consisting of a number of cars. The motor cars must possess sufficient weight for traction and be equipped with motors which can furnish the requisite draw-bar pull. In general, care must be taken in projecting an electric road so to build it that it can extend in the future, and new requirements be met without difficulty.

An important role in this connection is played by the choice of the right gauge. As gauges of less than 1 m. are seldom met with, this paper only compares the meter gauge with the standard gauge. Only eleven companies sent replies to the above question, and from these the following general conclusions have been drawn:

1. The narrow gauge permits an easy rounding of sharp curves. With the present types of motor cars, with a wheel base of from 1.6 m. to 2 m., this advantage is not a very important one. It has been found that of sixty-one electric roads having curves of 20 m. radius or less, thirty-three employ the standard gauge, and only twenty-eight the meter gauge. This shows that the occurrence of a few sharp curves should not be sufficient cause to induce railway companies to adopt the narrow gauge.

2. There is less expense connected with the construction and maintenance of a narrow gauge than standard gauge. This, of course, only becomes of importance where the company builds its own roadbed, and where the same is of considerable length. The narrow gauge requires a smaller expenditure for roadways, the transportation of earth and general construction.

3. As the electric roads are feeling more and more the competition with steam roads, especially in the transportation of freight, it is to their advantage to use the standard gauge, as it enables the electric freight cars to traverse the tracks of the steam road, thus saving the cost of unloading, and vice versa. To permit this the following conditions, however, must be observed in the building of the street car line:

(a) There must be no curves of a radius less than 150 m.

(b) The rails must be so supported that they can resist at any point a moving load of 6,000 kg. at a speed of 30 km. per hour.

(c) There must be a clear space above the track of 760 mm.

(d) The track axes must be 4 m. apart.

(e) There must be no grades which would overload the motors for too long a time.

(f) Such brakes must be installed and such a speed must be be chosen on public highways that the train can be brought to a stop within the distance required by law.

It is worthy of note that a number of original narrow-gauge roads, in order to become more serviceable, have changed over entirely to the standard gauge, or have laid a third rail.

4. As the motors are mounted between the wheels of the motor car, it is evident that larger motors can be installed on standard-gauge cars than on those built for narrow gauge. To compensate for this difference it is often necessary to equip narrow-gauge cars with two motors, which entails a considerable expense. It has the advantage, however, that if one motor should break down the other one will still be able to propel the car. Besides a two-axle car more evenly distributes the weight and starts with less jar than a single-axle car. Furthermore, two motors and a series-parallel controller permit of a better regulation of speed. It is also possible to attach a trailer to a motor car equipped with two heavy motors, or even attach a freight car during those hours when passenger traffic is light. To do this same work on a narrow-gauge road, four-axle cars with four motors must be employed, which necessitates a considerable expense. It is also more advantageous to use larger motors running at a slower speed with the armatures mounted directly on the wheel axles and so avoid the use of reducing gears. Such motors can only be used on standard-gauge cars.

5. The use of large motors on narrow-gauge cars takes up all the room between the wheels. Thus the accessibility to the various parts is made more difficult, which is a great disadvantage. The motors are further exposed to a greater extent to the water thrown up from the track during travel, as the space beneath the motors is too small to allow for the provision of proper guards.

6. The small space also forbids the mounting of air pumps for the use of air brakes alongside of the motors, and in any case the arrangement of the brake mechanism is less convenient on narrow gauge than on standard-gauge cars, on account of the crowded condition between the wheels.

7. The standard-gauge cars are also more stable than narrow-gauge cars. In the latter cars with longitudinal seats the wheel boxes become very objectionable.

8. In conclusion, a few remarks should be addressed on this subject to the owners and maintainers of highways who are in the habit of advising the railway companies to build narrow-gauge roads because they take up less room than those of standard gauge. This is an erroneous idea, however, as experience has shown that other vehicles will not use the narrow-gauge tracks, but travel alongside, and thus take up a great deal of valuable space on the roadway. As the narrow-gauge cars have the same width as the standard gauge ones, the space taken up by them is the same. There will, furthermore, be fewer collisions between vehicles and cars on broad-gauge roads, as the former are kept further away from the gauge line.

From the above it will be seen that for electric street railway service the standard gauge possesses many advantages, and is more commonly employed. I should not recommend the change to the narrow gauge, which would exclude the possibility of running street cars over steam railroad tracks.

* Abstract of report read before the International Tramway Congress, Paris, September, 1900.

PROGRESS IN ELECTRIC LAMPS.*

BY PROF. ANDRE BLONDEL.

The object of this paper is to pass in review the improvements realized up to the present, and those still to be hoped for, in arc and incandescent lamps.

Progress in Arc Lamps.—During the past 10 years great strides have been made both as regards the theory and the construction of arc lamps. Our theoretical knowledge of the properties of the arc has greatly increased. The measurements of M. Violle have shown that the maximum temperatures reached in the arc are 3,500° C. at the positive, 2,700° C. at the negative carbon, and also that in a closed space the brightness and the temperature of the crater are constant. Again, after a discussion, joined in by many authorities, it seems now settled in conformity with the present author's conclusions that the back EMF. in the arc exists only as rising from the arc's resistance, which can be considerably modified by the addition of salts to the crater. Mrs. Ayrton's experiments have connected by simple laws various phenomena of the arc; in particular they have shown that the energy consumed is a linear function for each diameter of the carbon. That the apparent resistance varies not only with the diameter of the carbons and the length of the arc, but also with the nature of the carbons and the surrounding gas has been shown by various experimenters. Mr. E. Wilson, repeating an experiment by M. Cailletet, has shown that the brightness of the positive carbon diminishes when the pressure is increased, and that by the withdrawal of gas a carbon mist is produced. M. Le Chatelier has attributed the constancy of the temperature of the crater to the presence of fusing carbon there. In addition, the author's experiments have shown that in free air the brilliancy of the arc increases with the current,

*Abstract of a paper read at the International Congress of Electricity at Paris. From the "Electrician," London.

Digitized by Google

and passes from 150 candles per square millimeter for small arcs to 220 candles per square millimeter for powerful arcs. Mrs. Ayrton, in her researches on the hissing of the arc, discovered that the hissing is caused by the advent of oxygen at the crater, and that the phenomenon does not occur below a certain current density, and is preceded by Trotter's phenomenon of the rotation of the arc on itself.

As regards the alternating-current arc the author has given a detailed analysis of its periods of lighting and extinction, and of its current and voltage curves; he has shown the parts played by the resistance and the self-induction of the circuit, the conductivity of the core, and the form of the EMF. curve of the generator.

The electric arc does not conform to Ohm's law, for increase of current produces widening of the arc, and consequently a diminution of the resistance. This leads to instability, which must be guarded against, on a constant-potential supply, by the inclusion of a resistance in series. This instability was studied by the author in 1891 by drawing "characteristic curves of extinction," in which the potential difference between the lamp terminals was plotted for various currents.

As regards the mode of regulation, the differential system seems now universally admitted to be the best. We may take with the minimum voltage of 30 volts for the arc a potential drop of 1.5 volts in the steadying resistance for alternating arcs, and with 33 volts a fall of 3.5 volts to 4 volts in the resistance for continous current arcs. The use of shunt-lamps presents some advantages over the differential system; the lamps are simpler; there is no risk of burning out by too strong a current; and they permit of easier regulation of the current within wide limits.

The oscillographic study of the extinction of the arc without additional resistance, shows it to take place slowly, the phenomenon requiring about $\frac{1}{10}$ second, or even more for its completion. This indicates that with quick-acting and sensitive mechanism the normal arc may be uninterruptedly maintained with only small steadying resistance in series. The inertia of the moving parts leads to hunting however, unless the vibrations set up are rapidly damped by a dash-pot. In the best modern lamps, air dash-pots are employed, and the adjusting mechanism has reached great perfection. Arc lamps have numerous constructional conditions to satisfy. They must be able to stand rough handling and every weather, and must be capable of easy and quick replenishment and repair. It is noticeable that of recent years there has been a tendency to revert to the use of clockwork mechanism on account of its great sensitiveness and small consumption of energy. As for motor mechanisms, they are rather complicated when continuous currents are used, but with alternating currents assume various elegant forms of the type of a metal disk embraced by electro-magnets of suitably differing phases. With certain types of mechanism in alternating current lamps the self-induction of the regulating coils tends to reduce the sensitiveness. This self-induction effect might be compensated, as M. Claude has suggested, by proper condensers. The self-induction, however, tends also to keep the impedance almost constant, in spite of variations of the resistance of the coils through temperature alterations, and so gives the alternating-current lamp some advantage over the continuous-current lamp. In the latter lamps ingenious temperature compensators have been adapted, but these unfortunately leave uncorrected the variations of the resistance produced by the shortening of the carbons. Improvements in mechanisn have brought many good double carbon lamps into use, among these the Crompton-Pochin, Brockie-Pell, and Korting and Mathiesen lamps may be mentioned. The author has for a long time considered that these lamps are very efficient as regards the utilization of the energy supplied. Besides this they require little labor and are economical in carbons.

Modern methods of lamp grouping differ greatly from the old system, in which the employment of isolated lamps was necessary. One modern tendency is, however, to use high-voltage enclosed lamps working directly at 110 volts; another is to use, as of old, two lamps in series, each absorbing from 30 volts to 35 volts. In both these cases the steadying resistance is important. But by the construction of differential lamps the importance of the steadying resistance is minimized. Low-voltage lamps have been in use since 1889, but it was not till after 1897, when the Hegner (Volta) lamp appeared, that the low-voltage lamp entered largely into industrial practice. Siemens & Halske, as also Korting & Mathiesen, in their low-voltage lamps use, at starting, a high resistance which is afterwards gradually removed. With these the fear arises that, in spite of the perfection of the mechanism, certain circumstances may lead to a dangerous increase of the current. Hegner, using also differential lamps, but without special mechanism, puts three in series with an automatic rheostat of four parts, which are removed successively as the lamps get started, thus securing a more stable and less dangerous arrangement than the former. Still more recently Vigreux and Brillé have proposed a special mechanism on the differential system which without springs, weights or frictional appliances, can produce a very rapid recoil of the carbon if the arc becomes shorted. The advantages of these low-voltage lamps are that they enable a better distribution of illumination to be effected, and that they are more economical as regards consumption of energy. Against these advantages must be set, however, the heavy initial expense, the complication and delicacy of the mechanism, and the necessity for carbons of very special quality.

With these lamps, grouping by threes is called for only on short, small resistance circuits. When large areas are being supplied the leads furnish sufficient steadying resistance for the usual arrangement of two arcs in series. In any case it is only on circuits at 110 volts and when sub-division of the illumination is desired, that low-resistance lamps are specially useful. When, however, the distribution is made at 220 volts, and especially when 220 volts is to be substituted for 110 volts in an existing circuit, a reduction of the number of lamps under a given voltage should rather be aimed at. The solution of this problem is afforded by the enclosed arc lamp.

Illumination by arc lamps in series, with both continuous and alternating currents, is still much in vogue in the United States, but has been almost completely abandoned in Europe on account of the lack of independence among the lamps and the dangers accompanying the use of high-pressure currents. A recent application in this direction in England consists in the employment of constant-current transformers and Ferranti rectifiers, and thus allows the use of lamps giving a better light distribution than alternating-current arcs. The pulsating current produced is, however, as dangerous as alternating current. On the Continent commutator transformation to continuous current, or the use of alternating-current lamps with reflectors, is preferred.

The enclosed arc lamp did not assume importance till 1894. It is characterized by having a very long arc using a tension of 75 to 80 volts. In the Marks (or Jandus) lamp the arc is surrounded by a double globe, the inner one of which possesses a valve (check-gas plug), which permits expansion of the contained air. The outer large globe is protective, and becomes filled with gas from the inner globe. In these circumstances the carbons are consumed very slowly, and the arc itself is modified in character—the upper positive carbon is, through rotation of the arc, scarcely hollowed, the lower negative carbon is plane, while their normal distance apart is 8 mm. at 80 volts. The mechanism of all makes of these lamps is of the most rudimentary type. And since the carbon consumption is small the displacement of the luminous spot is very little. The advantages of these lamps are: their independence of one another, the ease of their application in 110 volts or 220 volts systems, the extreme simplicity of their mechanism, the employment of cheap carbons, the small consumption of the carbons, and the reduction in the amount of attention necessary. Their disadvantages are, on the other hand, the blue tint in the light, the variations of brightness which render almost necessary the use of a diffusing globe, the fouling of this by a silicious deposit, and the mediocrity of the light from large carbons. The disadvantages attending the use of alternating-current enclosed lamps remain still so numerous that this type of enclosed lamp cannot yet be regarded as a success.

The manufacture of arc lamp carbons has rereceived, of course, much attention. The old method of baking several times a paste of carbon powder treated with certain syrups is quite discarded; its products were of the highest excellence, but were very expensive. Now, gas carbon, selected carefully and powdered, is mixed with various proportions of lamp-black and tar; and sometimes, with a view to increasing the luminosity or the durability, chemicals are added. The paste, well worked up, is squirted, and finally, cooked at the highest possible temperature. Most European manufacturers give the positive carbon a core of carbon containing borates and silicates, and emitting into the arc a conducting vapor, which assists stability, lowers the hissing voltage, and gives a wide range of working tension.

In the United States, for home consumption only, an inferior kind of carbon is made from lamp-black and petroleum purified by acid. Such carbons must be made very soft, and must be plated with copper if intended for low-voltage lamps. The coppering of carbons has been abandoned in Europe, chiefly because the drops of molten copper affected the steadiness of the arc.

The density of average carbons varies from 1.30 to 1.35; the specific resistance varies from 0.005. to 0.1 in ohms and centimeters, and is generally about 0.008 or 0.0095. The cores usually contain 80 to 85 per cent. of carbon, 5 to 6 per cent. of water, and the rest is made up

Digitized by Google

of silicates and borates. There is, however, no good test for the quality of a carbon other than its actual use in a lamp.

The proper diffusion of the light is now effected more thoroughly than formerly by the use of reflectors, opaline globes, holophanes, diffusers, etc., and also by the employment of inverted arcs whose light is reflected from a whitened ceiling or from special reflectors.

The photometry of the arc lamp has lapsed into confusion, for the horizontal candle-power maximum candle-powers, the mean spherical and the mean hemi-spherical candle-power are in common use, as well as a so-called "nominal" intensity. In any case, it is difficult to compare the results of two experimenters, on account of the insufficiency of definition of the arc. It is necessary to specify not only the current and terminal voltage, but also the diameter of the carbons, the voltage between their points, the length of the arc, and the kind of core in use. Moreover, to attain uniformity in results, it is necessary that the same standard of candle-power should be used by all the observers and that the tint of the light from the arc should be properly taken into account. The author and M. Jigouzo have found, by the aid of the lumenmeter, that the illumination produced is increased by a diminution of the diameter of the carbon following a law less simple, however, than that of Schreihage; and that it increases with the voltage up to a certain maximum depending on the current density, and then diminishes again. This maximum varies from 10 lumens to 25 lumens (0.8 candle to 2 candles) mean spherical per watt for the continuous current, and from 5 lumens to 17.5 lumens (0.4 candle to 1.4 candles) for the alternating current. Wedding's experiments, by other methods, showed, besides the influence of the diameter of the carbon on the photometric curve, the direction of the maximum candle-power is raised towards the horizon when the current density increases, and at the same time the ratio of the horizontal to the maximum intensity increases from one-fifth to one-half. Finally, an all-round comparison shows that the consumption per Hefner candle of the mean hemi-spherical candle-power is about 1.1 watts in 200 watt alternate-current lamps or in 60 watt continuous-current lamps, and is 0.68 watt in 1,100 watt alternating, or 150 watt continuous-current lamps. This great difference is partially compensated by the replacement in alternate-current lamps of the steadying resistance by a self-induction coil.

In enclosed arc lamps, supplied with 75 volts to 80 volts, the arc is perpetually undergoing irregular displacements, but the total luminous flux varies little. The diffusing globe absorbs 30 per cent. to 40 per cent. of the light produced. The yield of an enclosed arc seems to be about two-thirds of that of a good open arc lamp of the same power. The measurements by Wedding, Gérard and De Bast, have shown that the enclosed arc is not more economical than an incandescent lamp. Yet other experimenters, Friedman, Burrow and Rapaport, by reducing the diameter of the carbons, have shown the reverse. Still, the enclosed arc seems notably inferior to the open arc with regard to the energy consumption. Undoubtedly, with alternating currents the enclosed arc is considerably inferior to the ordinary incandescent lamp.

Progress in Incandescent Lamps.—The uniformity in the manufacture, the efficiency, the durability, and the price of incandescent lamps, have all altered for the better. The carbon filament lamp remains easily the most-used form of the incandescent lamp. It is usually employed in sizes of from 8 candles to 36 candles, exceptionally from 50 candles to 100 candles. The yellowish light it affords is rather in their favor than otherwise.

From the theoretical point of view it is regrettable that the rating of lamps by the method, proposed in 1899,by M. Crova, by defining their degree of incandescence, has not been applied in practice. This method makes easy the determination of the temperature of the filament. According to Weber this temperature reaches from 1,565 degs. C. to 1,588 degs. C. and even 40 degrees higher for lamps with larger filaments. Le Chatelier finds the temperature to be about 1,800 degs. C., while Janet deduced 1,610 degs., to 1,720 degs. for 16-candle lamps at 65 volts. Le Chatelier's method, in which the intrinsic brilliancy of the filament is assumed to depend only on the temperature and the condition of the surface of the filament, is open to objection on account of the evident transparency of the material of the filament. The increase of resistance with temperature is greatly concerned with the structure of the filament; for Howell has shown that the resistance of the core of a filament diminishes as the temperature increases, while the resistance of the layer of deposited carbon, like that of graphite, increases with the temperature. Hence it is possible that the resistace of a filament at some temperatures becomes stationary or possesses even a negative temperature coefficient.

On the whole the last 10 years have witnessed few changes of importance in the manufacture of incandescent lamps, but very great improvements in every detail of the complete lamp have taken place. The modern process of "squirting" cellulose dissolved in zinc chloride, alcohol-ether, sulphuric acid, etc., to form the filaments have almost completely replaced the old processes of Swan and Edison for ordinary filaments. For very large filaments a carbon paste similar to that used for arc lamp carbons is usually employed. The carbonization of the raw filament by incandescence in the hydrocarbon vapor remains still almost essential because it retards the blackening of the globe of the lamp, and permits, of a great modification of the resistance of the filament, the conductivity of the deposited carbon being eight or ten times that of the body of the filament. Unfortunately this change of resistance is still found to be difficult of regulation. Nowadays also the vacuum is much more nearly perfect. Powerful mercury pumps follow the application of mechanical air-pumps when these have reduced the pressure to half a millimeter of mercury; or sometimes, a process of chemical exhaustion replaces the mercury pump. The attachment of the filament to the leads, too, has been changed, perhaps for the worse, by the adoption of a process which bakes on to the joint a paste of carbon and tar. Nickel and ferro-nickel leads have been tried, but it seems better instead of entirely replacing the platinum to make the platinum portion of the leads as short and thin as possible.

Least progress of all has been made in the light-yield, referred usually to the maximum horizontal candle-power. Normally, the mean consumption is 3.5 watts per bougie decimale, unless the lamp is used at higher pressure than its proper voltage. Weissmann and the author by the use of low-pressure lamps have reduced safely the consumption to 2.5 watts per candle. The increase in the number of the 220 volt systems has caused manufacturers to develop a single-filament lamp working directly at 220 volts, but the construction of these lamps is more difficult, and variations of voltage have more effect than in the case with the lower-pressure lamps. These lamps, too, have proved less durable than the corresponding 110 volt lamp, they cannot be made to give satisfactorily low candle-powers, while their expenditure of energy per candle-power increases rather quickly with time. The future high-voltage lamp will probably employ a filament of higher resistance than the carbon filament.

Many experimenters have endeavored to make filaments of other refractory substances than the carbon, such as the carbides of boron, silicon, aluminum, calcium, etc., but have not attained complete success. Langhans uses a filament of cellulose mixed with powdered boron or silicon; Maxim uses a modified form of carbon filament which is made from a crystalline carbon powder made into a paste with tar. Welsbach makes filaments by heating a platinum wire in an atmosphere of hydrocarbons, water vapor, and osmium anhydride. The latter filaments, though very efficient, are expensive and can be used only with pressures of from 20 volts to 30 volts. The use of the rare earths in this connection seem very promising: Various investigators have endeavored to cover carbon filament with these substances both by electro-chemical processes and by the application of pastes. The chief difficulty in the way seems to be the difference between the coefficients of expansion of the carbon core and the deposited oxides. Chromium, tungsten, platinum, iridium, etc., have all been used to replace carbon, but with small success. Welsbach, however, has made a filament of thoria, deposited on platinum or osmium, which consumes only 1.5 watts per candle, but the lamps so made are very expensive.

Jablochkoff, in 1877, and Nernst, in 1897, made use of the property, described by M. Roux, which the oxides and analogous substances possess of becoming conductive at a fairly high temperature. Nernst has made the necessary preliminary heating automatic by placing a spiral platinum wire near the filament; he uses also oxides of greater conductivity than ever used before. These lamps give a very white light, produced by the expenditure of energy, at the rate of 1.75 watts per candle in a 25-candle lamp, and 1.00 watts per candle in a 100 candle lamp. The presence of air, or at any rate an oxidizing atmosphere is necessary to prevent electrolytic decomposition of the filament. It is to be feared that variations of voltage may have rather a large effect, and in any case, a steadying resistance is necessary. Lamps of less than 25 candles, or less than 110 volts, have not yet been made, but high-voltage lamps are easily obtainable.

The rating of incandescent lamps varies from country to country. In France the "bougie decimale," and in Germany and America the Hefner, are the common units of illumination. In France the horizontal candle power perpendicular to the loop of the filament is measured; in other countries the mean of the candle-powers in several directions is taken. The German Electrical Association lays down that lamps should bear an indication of the power and voltage to within 2 per cent., and that the life of a lamp be defined by the time in which the candle power falls 20 per cent.

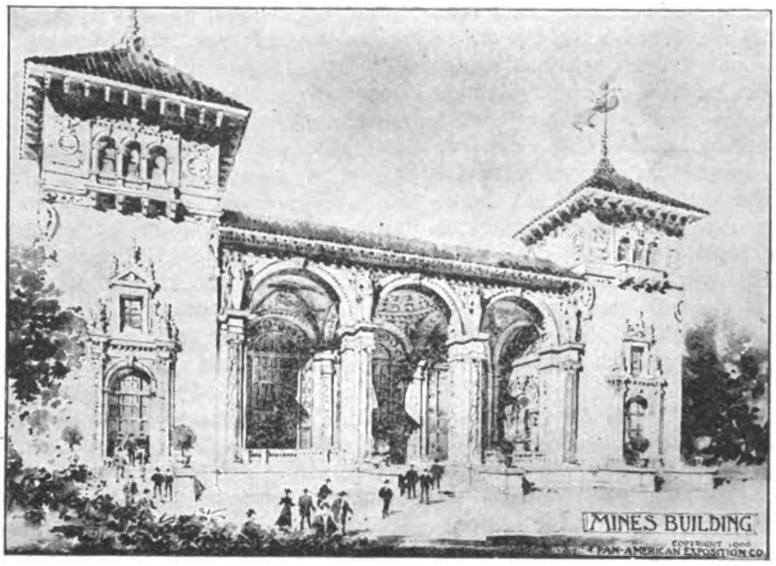
THE MINING EXHIBITS AT THE PAN-AMERICAN EXPOSITION.

No feature of the Pan-American Exposition will be of more importance than the exhibit of mines, and metallurgy. The building to be devoted to these exhibits is one of a group of three magnificent structures, arranged in the form of a horseshoe, at the western boundary of the Esplanade. The Mines Building is the southernmost of the group and is connected with the Horticultural Building by one of the conservatories whch flank the Horticultural Building on the north and south. It is 150 feet square and at each of the four corners it has a square tower 90 feet high. The eastern facade looking upon the Esplanade, shows three high recessed arches between the towers, forming an open loggia elaborately and beautifully ornamented with plastic detail and decorated in brilliant colors. From this loggia are the main entrances to the building. There are also entrances in the corner towers. The ornamental detail is very picturesque and interesting. The design is by Peabody & Stearns of Boston.



Mines Building at the Pan-American Exposition.

Never was the science of metallurgy or skill in mining more highly developed than in the present day. The golden decorations of King Solomon's Temple are estimated to have cost $250,000,000. Ever since the account in the Book of Genesis of finding gold along the river Pison, a stream which flows from the Garden of Eden, the seeking for and mining gold has been one of the most fascinating industries. The production of gold throughout the world during the present century has steadily increased. The production in the United States in 1899 amounted to $72,500,000 while that of the whole world is given at $315,000,000 thus giving the United States the first position in production of gold of any country. In the matter of copper the United States produces 223,000 tons annually, or more than one-half of the world's output. The United States and Mexico are the two greatest silver producing countries. In other mining productions, the commercial value of which is considerably greater than that of the precious metals, the countries of Pan-America also lead the world. During the last year the coal output of the United States reached the enormous amount of 225,000,000 tons. This, as compared with Great Britan's output of about 200,000,000 tons and Germany's 100,000,000 tons, makes the question of the future production of coal, considering the rapid increase in America and the fact that European production has reached its limit and is already declining, especially noteworthy at this time. The Canadian output of coal and iron is an item of great importance. The near proximity of iron and coking coal and the proper fluxes gives Canada a great advantage in the manufacture of iron and steel. The advancement of these industries in North America during the past decade are phenomenal, the total production of the United States last year amounting in value to $413,758,414 and of non-metallic substances to a total of $601,872,631.

Besides the ordinary mining industries there are many others with which the general public is but little acquainted. Southern California has immense deposits of asphaltum which are merely waiting the necessary capital and transportation for their development. California is also producing tin ore containing from 3 to 6 per cent. of metal. The value of this may be estimated from a contrast with the Tasmania mines which assay about 2 per cent. A great many productions, such as diamonds, amethysts and other precious stones; mica, asbestos, zinc, aluminum, peat and salt belong also in this classification. The prosperity of nearly all the countries of the Western world is largely due to their mineral wealth. Much of the manufacturing depends for success upon these productions and the ease with which they are obtained is what gives these Western States and nations the advantage over older countries in this respect. The exhibit of mines and metallurgy at the Pan-American Exposition will illustrate graphically these advantages and will add greatly to the general knowledge upon the subject.

Electric Power and Fire Engines.

The chief fire engineer of the New Orleans, La., department has figured out that the relative running cost as between a three-horse hitch engine of the first class and an electric power engine is $60 a month for the former and $27 for the same period for the latter. These figures show a clear gain of $33 per month, and $400 per annum, in round figures for the electric power engine.

LONDON NOTES.

(From our London Correspondent.)

Electric Traction on the Underground.

It has now been decided that all tenders and schemes for the conversion of the Metropolitan and Metropolitan District railways to electrical working must be lodged in London by December 1. The matter is in the hands of the Electrical Traction Joint Committee, which consists of representatives of the two companies. The present increasing unpopularity of the railways, and the growing popularity of the Central London are rendering it imperative that the change to electricity must be made at once if it is to save the concern.

The City of London Electricity Supply.

In the annual report of Mr. Voysey, the City of London Corporation's electrical inspector, it is stated that there are now in the city district 507 arc lamps. The police reported 562 lamp failures, and the inspector 356, and penalties amounting to about £173 were inflicted. It is remarked that the Corporation is still without means for testing the value of the public lighting supply, as the Board of Trade has not formally approved of any type of instrument for the purpose. The question of lighting the side streets by electricity still hangs fire. Important experiments were made some years ago with a view of deciding what would be the best method of suspending fittings, and whether arcs or incandescents should be employed, and what candle power would be requisite for effective illumination of these dull narrow streets and courts which abound within the city district. During the year the inspector reports that there were two important interruptions in the supply of energy to private consumers; one affected the entire city area, and the other only a portion of it. On eleven different occasions, however, the pressure was defective. Efforts are being made to compel the City of London Electric Lighting Company to provide adequate means for the inspector to ascertain how far the company complied with its obligations in respect of the maintenance of a proper pressure of supply to private consumers. Arrangements have been made for the testing of meters at the Guildhall without expense to the Corporation.

Accidents in Electricity Works.

Great precautions have been made for some years past to have posted upon the walls of English electricity works full instructions showing the most approved methods of dealing with those who are affected by electric shock by any mishap or other. It is, however, remarkable that those in whose interests they are drawn up with explanatory photographs, pay little heed to them; hence occasions have arisen when assistants have not known how to set to work upon an unfortunate comrade. It is, however, perfectly true that in other cases these rules have been carried out with very satisfactory results. Only a short time ago a young switchboard attendant working at the switchboard of the Blackheath and Greenwich polyphase station was killed by a shock, and in the course of evidence at the inquest the electrical engineer in charge of the works admitted that although (after a previous similar accident to a lad in February last), the Home Office Dangerous Trades Committee sent certain regulations to prevent accidents in elec-

Digitized by Google

tric generating works, he had not even read them all.

Higher Voltage Supply.

In certain of the London districts the large Electricity Supply Companies when desiring to change their consumers over from 100 to 200 volts have been seriously hampered by a few consumers here and there who have held out doggedly against any alteration. These obstructive consumers have had to be dealt with in such a way that they pay the maximum charge per unit while their neighbors are supplied at about 3d. per unit less. This move on the part of the companies has led the London County Council to make a counter move on behalf of consumers with a view of getting the maximum permissible charge reduced from 8d. to 5d. whatever the voltage. The Board of Trade has been duly appealed to with this end in view, but it has deferred any action in regard to the matter at present because it has under consideration the question of imposing a sliding scale of charges upon all electric lighting companies throughout the Kingdom.

THE ELECTRIC STATION OF THE EIFFEL TOWER.

BY L. FOURNIER.

Translated for ELECTRICITY from "La Vie Scientifique, Paris, France.

Electric current is furnished the projectors and the beacon on the Eiffel Tower through a system of wiring which conforms to the edges of the tower.

Besides the innumerable light rays sent in all directions by this means, the Eiffel Tower is provided with a powerful system of illumination which at night gives it the appearance of being on fire; the arches and the outer framework, together with the first and second stories, all decorated with multi-colored lights, appear to form a garland for the neighboring palaces, and increase the effect of their illumination.

Having once witnessed this spectacle, we realize the enormous amount of electricity necessary to furnish light for all these thousands of lamps, and we become curious to know where the generators are to be found.

If we walk up to the first story we will find in the south pillar a stairway which leads to an underground room roofed over with glass, containing the machine which furnishes power for the elevators and current for the lamps; this installation is made up of five electric generator groups, each of different power.

The two largest comprise a compound Carels high speed engine, making 325 revolutions per minute, and operating through a Zodel coupling a Sautter-Harlé dynamo of 230 kilowatts at 130 volts. It is a continuous current multipolar dynamo, provided with six sets of carbon brushes, each set containing 17 individual pieces.

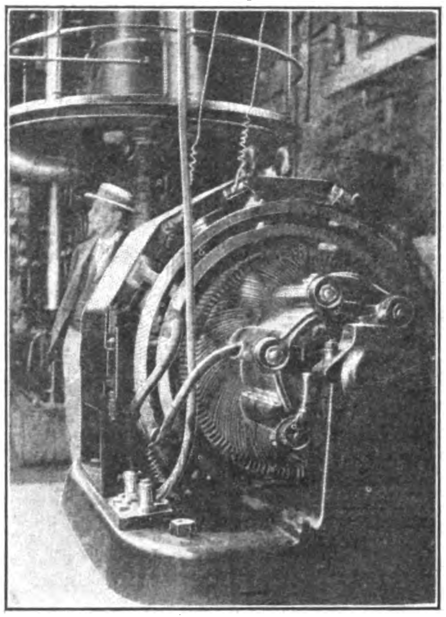
The field is connected in a shunt circuit and contains six pole pieces, between which are placed six additional complementary poles connected in series and serving as magnetic field governors, in other words, to maintain a constant current at the brushes whatever may be the demands on the generator. Two smaller generators are placed near them, each driven by the Sautter-Harlé type of vertical compound engines driving through leather belts. The output of these dynamos is 52 kilowatts at 130 volts; they have an armature speed of 350 revolutions per minute, there are four pole pieces and four sets of carbon brushes each containing ten units; these as well as all the other dynamos built by Sautter-Harlé & Company are furnished with pillow block ring oil boxes containing anti-friction metal axle bearings, composed of an alloy of copper, tin and antimony.

The axle bearings are pivotally suspended to allow the axle to maintain a free position without fear of heating. The magnetic circuit throughout is a steel casting.

The four dynamos just described can be connected in parallel at the switchboard, and they furnish all the lighting current for the Tower.

The fifth generator group is used for day work only, to drive ventilators and furnish current for lighting the cellars and the restaurant kitchens.

The driving power is a Sautter-Harlé single cylinder vertical engine with a leather belt connection to a four pole dynamo of 8 kilowatts



ONE OF THE EIFFEL TOWER LARGE DYNAMOS.

at 130 volts. The construction is practically the same as in the one already described.

The cable conductors of the day circuit lead from the generators to a two pole circuit breaker and switch by which the current may be switched into the day circuit or to the switchboard.

The distributing switchboard was constructed by Mornat and Langlios under the superintendence of the electrical department of the Eiffel Tower; the material of which it is constructed is white marble 5¼ meters long by $2\frac{7}{10}$ meters high with three panels. The center panel contains the connecting and regulating apparatus comprising an ampere meter, a cutout, and a rheostat dial for each of the four principal generators, and in addition there are two voltmeters, one of them is connected to the bus bars and the other may be placed in circuit with the terminals of each of the four dynamos by means of a four-way switch.

Both the ammeters and the voltmeters are of the dead beat type and were constructed by Chauvin & Arnoux.

The ordininary lighting circuit terminates at the left hand panel; there are fourteen of them branching to all parts of the tower, beacon, projector No. 1, also No. 2, Russian-French restaurant, outside stairway, north, south, east pillars, etc.

In each of these circuits is to be found a bipolar circuit breaker and an ampere-meter.

The illuminating circuits are connected to the right hand panel of the switchboard, in which are placed those lamps that are mounted on reflectors and located along the outer edges of the tower. There are fifteen of these circuits corresponding to the four sides of the tower, the staircases, the roof edges of the first and second stories etc.

These fifteen sections are independently manipulated at the board and comprise 4,200 incandescent lamps of ten candle power each, while the ordinary lighting circuits first mentioned comprise the beacon light, the three projectors, 2,000 incandescent lamps of 10 candle power each, with the exception of a few of 16 candles, and 24 arc lamps of 8 amperes, altogether requiring 1,100 amperes at 130 volts, while the maximum capacity of the board is 2,500 amperes at 130 volts.

The total number of circuits in the Eiffel Tower system therefore is twenty-nine; all conducting cables are insulated and strung on two and three petticoat insulators.

PROFESSOR PERRY'S PRESIDENTIAL ADDRESS.

[From our London Correspondent.]

On Thursday, November 8, Professor John Perry, F.R.S., delivered his inaugural address for the 1900-1901 session to the members of the Institution of Electrical Engineers.

On the subject of standardization he stated that his hearers "must have noticed that the American engineers, who surely deserved the character of being practical idealists above all other engineers, are the men who are most imbued with notions of standardization which lead to cheapness of manufacture, and they are also the men most alive to the necessity for occasional extensive scrapping of types of machinery when they become even a little antiquated." Other extracts are as follows: Our knowledge of electrical phenomena must be quantitative to be of practical use; we must be able to calculate. Mathematics is the science of calculation and we must, therefore, be able to employ, and we all do necessarily employ, more or less mathematics every hour of our professional lives.

"As for the man who does understand electrical problems, he remembers that there was a something called a study of mathematics at his school, that he did pass certain examinations with much difficulty and tribulation, that the subject had no real meaning to him even when he was supposed to know it, and he now hates the sight of anything that looks like mathematics.

"Quite recently one of our most eminent members declared to me that he had not really grasped the reason for small economy at a power station when there is a small load factor, until he studied the common sense mathematical form which has been given in a recent publication. And yet he is a man who has heard, read and talked much on this subject.

"The fact is, mathematics ought to be the natural language of the electrical engineer, and at present it is a foreign language; we cannot read or write or think in it. We are at the beginning of our development,

Digitized by Google

like monkeys whose necessities have increased faster than their powers of speech."

The production of electricity from coal, terrestrial magnetism and several other topics were briefly touched upon in the professor's very interesting address.

The New York Electrical Society.

The New York Electrical Society held its 209th meeting at the College of the City of New York on November 16th, when, before a very large and most appreciative audience, Mr. C. P. Steinmetz delivered a lecture on "Alternating Current Engineering." It may be said at once that no more valuable or interesting lecture has ever been delivered before the Society. In the course of about an hour and a half, supplemented by replies to suggestions, Mr. Steinmetz treated of the development of the alternating current for power and lighting purposes; its application for long distance work; its relation to continuous current local supply; questions of railway work; frequency, voltage, regulation, etc. While treating the subject broadly, Mr. Steinmetz presented a number of new facts and cleared up many obscurities in regard to the nature and use of alternating currents. At the close of the lecture and of the discussion, in which Messrs. Dunn, Henshaw, Burnett and Williams participated, Mr. Steinmetz, in response to a unanimous request, promised to put the lecture into written form so that it may be published by the Society.

The following is the list of members elected at the 209th meeting: H. S. Arnold, C. F. Splitdorf, G. H. Hill, J. S. Humbert, Chas. Arthur Hanna, David H. Darrin, M. R. Hutchinson, C. Howard Parmly, C. W. Obert, Robert A. Fliess, Howard Richards, Jr., Edward R. Knowles, New York City; H. G. Osburn, Hoboken, N. J.; Harry B. Naylor, Newark, N. J.; W. W. Morse, West Orange, N. J.; E. M. Archibald, Ampere, N. J.

LEGAL NOTE.

Upon application of the American Loan and Trust Company of Boston, the Dallas Electric Company of Texas has been placed in the hands of a receiver by Federal Judge Meek. The receiver is E. M. Reardon, who has given bond for $20,000, and taken charge of the property. Default in the payment of interest on $300,000 worth of the Dallas Company's bonds, which were held by the Boston corporation, was the cause of the action.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended November 15:

Antwerp, 32 cases, $3,986; Argentine Republic, 45 packages, $2,585; Australia, 164 packages, $3,831; 37 cases, $10,355; Bremen, 7 cases, $469; British Guiana, 274 packages, $2,902; British West Indies, 13 packages, $340; British Possessions in Africa, 264 cases, $14,702; Central America, 55 packages, $2,396; Cuba, 9 packages, $180; 186 packages electric railway material, $15,448; Dunkirk, 12 packages, $4,157; Fiume, 1 case, $22; Glasgow, 196 packages, $53,776; 29 electric cable reels, $13,720; 3 cases, $372; Hamburg, 70 packages, $3,843; Havre, 89 packages, $4,984; London, 210 cases, $5,006, 81 packages, $7,389; Liverpool, 133 packages, $6,978; Mexico, 190 packages, $239; 3 cases, $642; New Foundland, 9 packages, 203; New Zealand, 3 packages, $110; Nova Scotia, 34 cases, $1,098; Peru, 6 cases, $598; Santo Domingo, 2 cases, $34; Southampton, 6 cases, $365; 8 packages, $277.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

The Lakefield Portland Cement Company, of Lakefield, Ont., will have its works operated entirely by electricity. The water power is situated about 5 miles from the works, to which electric current will be transmitted at a pressure of 100,000 volts, by a 600-horse power generator, and, transformed at a sub-station at the works.

The Montreal Electric Street Railway Company has introduced an innovation in street railway building in the reconstruction of its track on St. James street in that city. Steel ties, to which the rails are firmly bolted, are used. The system has been tried in India and various countries in the tropics, and it is understood has given much satisfaction.

The initial installation at the works of the Chambly Manufacturing Company, at Chambly, Que., from which point current is transmitted direct to the city of Montreal, 17 miles distant, consisted of four two-phase generators of 2,000 kw. capacity each, wound to generate current at 12,000 volts. The plant was so designed, however, as to provide for the installation of eight machines of the same capacity. The demand for power has been so great that the Chambly Company has found it necessary to install the additional equipment originally provided for, and accordingly the four additional generators will be wound for 2,200 volts, and by means of transformers the current will be stepped up to 12,000 volts for distribution over the circuits.

PERSONAL MENTION.

Mr. Frank Jarvis Patten, the inventor of the multiplex telegraph system, which was purchased by the Western Union Telegraph Company, and of the gyroscope, used for giving the position of a vessel in mid-ocean, died suddenly last week in this city.

Mr. E. J. Chebas, an electrical engineer of Santiago, Cuba, has been spending some time in Pittsburg, Pa., in relation to the establishing of an electric light plant at Santiago.

Mr. Frederick W. Royce, known as an inventor, electrician and veteran telegraph operator, dropped dead from apoplexy in Washington, D. C., November 16.

Mr. Joseph C. Lugar, general superintendent of the Wilmington, Del., City Railway Company, is visiting Chicago and other Western cities where he will study the trolley systems.

INCORPORATIONS.

The Richmond Electric & Power Company, Frankfort, Ky. Capital stock, $9,000.

The Railway Electric Refrigerating Company, New York City. Capital stock, $6,000,000.

The Consolidated Safety Third-Rail Electric Company, New York City. Capital stock, $100,000.

The Franklin Electrotype Company, New York City. Capital stock, $5,000. Directors: William L. Columbine and J. T. Allaire, Brooklyn, and T. H. Allaire, Red Hook, N. J.

The American Light, Power & Transportation Company, Trenton, N. J.—to operate electrical works. Capital stock, $1,000,000. Incorporators: W. A. Jones, E. D. Conklin and F. P. Crain.

The Newburgh Light, Heat & Power Company, Newburgh, N. Y.—to manufacture gas and electricity. Capital stock, $500,000. Directors: J. L. Wilkie. W. B. Goodwin and Moses Ely, New York City.

The South Boston Electric Light & Power Company, South Boston, Mass.—to maintain and operate an electric plant. Capital stock, $200,000. Incorporators: R. W. Lawson, J. J. Lawson, R. S. Barbour, J. Stebbins, all of South Boston; R. H. Easley, of Houston; E. Schaefer, of Lynchburg.

The Dunsbach Ferry Electric Company, Half Moon, N. Y. —to furnish electricity for lighting, heat and power purposes in Watervliet and Half Moon. Capital stock, $100,000. Directors: Henry W. Miller and Alfred H. Dobson, Utica; Francis W. Marsh, Ebenezer Burr and John C. Chamberlain, Bridgeport, Conn.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 13, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

661,516. Trolley. Henry S. Goughnour, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Filed March 21, 1900.

661,600. Trolley Wheel. Thomas I. Duffy and Charles S. McMahan, Chicago, Ill.; said Duffy assignor to said McMahan. Filed July 16, 1900.

661,926. Toy Trolley-Car System. Charles F. Agor, Shrub Oak, N. Y. Filed July 5, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

661,505. Illuminating Device. Leonard Erikson, Boston, Mass. Filed March 17, 1900.

661,839. Dash-Pot for Electric-Arc Lamps. Thomas E. Adams, Cleveland, O. Filed May 7, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

661,719. Rectifier of Alternating Polyphase Currents. Louis H. Haynes, Newton, Mass. Filed Dec. 30, 1899.

661,742. Circuit-Controller for Electric Engines. Henri Letord, Orlando, Fla., and Joseph S. Letord, Kansas City, Mo. Filed Feb. 27, 1900.

661,771. Electric-Circuit Breaker. Benjamin P. Rucker, Philadelphia, Pa. Filed June 25, 1900.

661,880. Electric Brake-Controller. John C. Lincoln, Cleveland, O., assignor to Arthur L. Garford, Elyria, O. Filed Oct. 2, 1899.

TELEPHONES AND TELEPHONE APPARATUS.

661,578. Toll-Collecting Device for Telephones. William A Foss, Cleveland, O., assignor to the American Toll Telephone Company, same place. Filed July 26, 1900.

661,714. Telephone-Circuit. Isaiah H. Farnham, Wellesley, and George W. Davis. Revere, Mass., assignors to the New England Telephone & Telegraph Company, Boston, Mass. Filed May 11, 1900.

MISCELLANEOUS.

661,491. Emergency-Brake Switch. William M. Brown, Johnstown, Pa. Filed Oct. 14, 1898.

661,498. Electric Fuse. Joshua L. Cohen, New York City. assignor of fifty-one one-hundredths to Herschel P. Copeland, Jersey City, N. J. Filed Jan. 4, 1900.

661,518. Controlling Device for Electric Circuits. Edward W. Hammer, Chicago, Ill. Filed Aug. 31, 1899.

661,538. Brush-Holder for Dynamo-Electric Machines. Christian W. Kragh, Madison, Wis., assignor to the Northern Electrical Manufacturing Company, same place. Filed Sept. 11, 1899.

661,555. Fire-Alarm. Alfred A. Ross, Montgomery, Ala. Filed March 15, 1900.

661,588-661,589. Electric Welding Apparatus. Adolf F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company, same place. Filed June 1, 1899, Sept. 23, 1899.

631,616. Alarm and Releasing Mechanism for Fire-Engine Houses. Edward P. Matter, Alexandria, Va. Filed March 13, 1900.

661,666. System of Electric Train Control. Charles B. Martin, New York City. assignor to the General Electric Company of New York. Filed Oct. 23, 1897.

661,669. Connecting Conductors to Carbon Brushes. Albert L. Rohrer, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 22, 1898.

661,736. Fire-Alarm. Oskar Freymann, New York City, assignor of one-fourth to Charles Tolman, same place. Filed Nov. 17, 1899.

661,820. Electrical Apparatus. Martin Schupner, Nyack, N. Y. Filed June 16, 1900.

661,881. Electric Meter. Charles W. G. Little, Heckington, Eng. Filed Sept. 4, 1900.

REISSUE.

11,872. Traveling Contact for Electric Railways. Thomson-Houston Electric Company, Boston, Mass., assignee of Albert Wahl and C. A. Coffin, administrators of Charles J. Van Depoele, deceased. Filed Sept. 28, 1900. Original No. 495,413, dated April 11, 1893.

COMMERCIAL PARAGRAPH.

We are in receipt of a very handsomely gotten up catalogue issued by Manning, Maxwell & Moore, 85-89 Liberty street, New York, which contains over 700 pages of interesting reading matter and illustrations. This volume, which treats of metal and wood working machine tools and attachments should be in the hands of all those interested in this line of work. This well-known concern has in New York three large warehouses filled with machinery for prompt delivery. In Chicago they have a very complete establishment at 22-24-26 South Canal street, which is stocked with a full assortment of the latest improved machine tools for quick delivery. They have an office at 1005 Park Building, Pittsburg, Pa., in charge of a corps of able assistants, and one at 1020 Williamson Building, Cleveland, Ohio, where prompt attention will be given to inquiries.

Digitized by Google

THE TELEPHONE WORLD.

'Phones for Trolley Cars.

Superintendent Townsend of the Meriden-Southington, (Conn.) line announces that at an early date all cars of that line will be equipped with telephones, so that in case of delay or trouble the office and power station may be promptly notified. He says the order for the telephones has already been placed. They are made by the Connecticut Telephone Company of Meriden and are operated by raising a wire by a light pole to a wire paralleling the trolley wire. The system is the best so far developed, and will undoubtedly be appreciated by the public. The superintendent's house has already been connected by telephone with the office and power station, being part of the car system to be inaugurated.

The Greeley, Col., Independent Telephone Company, which has lately been incorporated by several prominent citizens of that city, has met with much success. An exchange has just been installed in Evans with twenty-eight telephones. The company has been granted a franchise in Greeley, subject to an ordinance which will shortly be granted. As soon as enough telephone poles have arrived work will be started on an exchange for Greeley. Already about 175 people have pledged themselves as subscribers. When the work in Greeley has been completed an exchange will be established in Easton, and so on until the system reaches all the principal towns of Weld County. The object of the company is to connect the surrounding towns with the county seat.

The Cumberland Telephone Company, which some time ago bought up all opposition and competition in New Orleans, La., and then almost doubled its rates, has won a victory over the Board of Trade and a number of individual citizens who brought suit before the State Railroad Commission against the concern. The commission refused to issue an order reducing the telephone charges in New Orleans, and now the Cumberland people may raise or lower the rates at will. There is great dissatisfaction over the decision, the business men contending that the city is now at the mercy of a grasping monopoly which will exist until the franchise runs out. The Cumberland Company owns two franchises covering the entire city.

The Dutchess County Telephone Company, with principal office at Poughkeepsie, N. Y., and having a capital stock of $125,000, recently filed articles of incorporation with the Secretary of State. The general route will take in the city of Poughkeepsie, the principal towns, villages and cities of Dutchess County, the State counties adjoining Dutchess County, and that portion of the State of Connecticut which adjoins Dutchess County. The directors are: A. A. McGlashan Myndert, J. Van Kleeck of New York City; H. A. Tucker, Asa Lippincott, of Brooklyn; George W. Sutton, John H. Scofield and Arthur E. Waldradt of New Rochelle.

The business of the Southern New England Telephone Company, says a New Haven, Conn., paper, is constantly growing and the officials are not able to keep up with the orders. The large force of mechanics are constantly employed in getting out new instruments and new stations are being equipped in all parts of the State. In September the company put in 253 new stations. In October the number was 221 and thus far this month 82 new stations have been established and there are 51 unfilled orders. This increase is not abnormal the company having maintained that gait for a long time.

There is quite a local interest manifested in the establishment of a telephone line in West Sumner, Me. To that end the Oxford Telephone Company has been organized with a capital of $800 to run a line through the towns of Buckfield, Sumner, Paris, Woodstock and Greenwood. Work has already begun and it will soon be complete. The company was formed as follows: E. H. Andrews, president; H. W. Dunham and S. F. Stetson, vice-presidents; G. A. Chandler, secretary; S. H. White, treasurer, and Geo. H. Plaisted, superintendent.

Preliminary steps have been taken to extend the Salt Lake City-Butte telephone lines to Boise, Idaho, by way of Pocatello and Blackfoot, Idaho. Connection will also be made by branch lines to Mountain Home and the Custer County mining camps.

A dispatch from Boston says of the entire output of telephones by the American Telephone & Telegraph Company for the ten months ending October 20, the Erie system has taken 29 per cent., represented in over 30,000 new subscribers; The average increase of the entire system in the United States, according to the output, has been 19 per cent.

The Exeter, N. H., Telephone Company has increased its capital stock from $2,000 to $5,000. A dividend of 6 per cent. was declared for the year ending November 1.

The differences between the town of Attleboro, Mass., and the Providence Telephone Company were lately settled, and the plans for a new exchange, made some time ago, will be carried out without delay. In four months Attleboro will have a modern exchange, and overhead wires will be removed from three miles of streets, the total length of the ducts being 20,000 feet. Each cable contains from 120 to 200 pairs of wires, and this indicates that ample provision has been made for increased demand for telephone facilities in Attleboro.

Cheap telephone service is one of the comforts of life in Kokomo, Ind., at present. A competing plant has been put in by a local company. The Bell Company up to the arrival of the competitor charged $3 per month for business houses and $2 for residences. The new company put the prices at $1.25 and $2. This came so nearly putting the old company out of the business that the latter is contracting for fifty cents per month, with either monthly or yearly contracts. The Citizens' Company still adheres to its original rate of $1.25, and has yearly contracts with 600 subscribers. The Bell Company never had more than 300.

The sub-station of the Chesapeake & Ohio Telephone Company at Georgetown, D. C., is rapidly nearing completion, and will most likely be ready by the latter part of the present month. It is stated that the company is anxious to have the plant in working order by the time Congress again commences its sessions. The wires for this section have all been put in order, and will require but a short time to connect with the new station.

R. E. Lee of New Orleans, La., representing the Cumberland Telephone Company, has lately been at Opelousas, La., for the purpose of placing an exchange there. At a meeting of the board of aldermen a franchise was given the company to operate in that place. Mr. Lee has met with much success. The company expects to begin operations there at once. At present the town has the Birtha Telephone Exchange in operation, which it is expected will fight the Cumberland people.

The Mexican Telephone Company has recently completed the extension of its metallic system in the City of Mexico. The entire business section of that city now has a metallic 'phone system whereas heretofore but a small area was thus supplied. The work upon the extension was commenced last spring, and has cost about $22,000, which sum has been paid from the earnings of the company.

The Home Telephone Company of Florence, S. C., celebrated its first birthday this month. In that city there are now 106 telephones, and the exchange can give on call more than 50 connections. This is exclusive of those small places where there are but two or three 'phones connected. The Home Company has prospered greatly, and the prospects for its future are very bright.

From Minneapolis, Minn., comes an announcement that the Northwestern Telephone Exchange reports a net gain of 397 subscribers in October, making a total number of 21,023 subscribers October 31. The Erie Telephone system, which includes this company, reports a net gain of 2,644 subscribers in October, making a total number of 137,214 subscribers of this system October 31.

W. D. Meadaris, manager of the Cumberland Telephone Company at Fayetteville, has been in Lynchburg, Tenn., with a view of establishing a local exchange. It is thought that the citizens of the town will give the necessary encouragement to the proposition, and that the exchange will be put in.

The Norfolk, Va., city council has decided that the Southern Bell Telephone Company may remain undisturbed in possession of its franchise, which allows it to fix rates as high as it wishes. The Southern Bell Company objected to the fixing of a maximum rate and recently increased its charges 100 per cent.

Samuel B. Rawson, of Elyria, O., president of the Home Telephone Company of Lockport, N. Y., has recently been looking after the construction work now in progress on the new line in Lockport. Mr. Rawson expressed himself as pleased with the progress the men are making and stated that it would be some time yet before the work of stringing the wires was taken up. The pole line in the central district will first be attended to.

In addition to conducting a general lighting and heating business one of the purposes of the Fruitvale Light, Power & Heat Company of Fruitvale, Cal., is said to be the establishment and operation of a telephone business.

Spencer, Mass., is to have a Citizens' Telephone Company to compete with the New England Telephone & Telegraph Company. It has been organized with a capital stock of $20,000, and its promoters have great faith that it will go through. E. P. Cutter of Spencer called on the promoters of the Citizens' Telephone & Telegraph Company of Worcester not long ago and talked over matters with them. His principal object was to find out how they were going to secure their franchise. It is not the purpose of the Spencer Company to ally itself with the Worcester Company at the start, at least, but it may eventually come to this. This would be greatly to the advantage of the subscribers of the Spencer Company for it would give them direct communication with subscribers in Worcester, which they will not get from a purely local company. The affairs of the two companies have not advanced far enough to settle on anything like this yet, but both being antagonistic to the New England Company, they would naturally be more likely to pull together. The yearly telephone rental in Spencer is now $25 and the new company claims to be able to rent telephones and give a good service for $10 or $15 a year. The promoters claim they already have the names of many people who will become subscribers. Mr. Cutter, who is one of the most deeply interested in the company, said he believed the company would be doing a good business in Spencer before long.

It was announced in Baltimore, Md., on November 15, that negotiations are being conducted looking to the absorption of the Maryland Telephone Company of that city, the Pittsburg & Allegheny Telephone & Telegraph Company of Pittsburg, Pa., and the Delmarvia Telephone Company of Wilmington, Del., by the Erie Telegraph & Telephone Company. The three former corporations are controlled by a Baltimore syndicate. The deal, it is understood, is being arranged by Alexander Brown & Sons and George R. Webb, president of the Maryland Telephone & Telegraph Company. Alexander Brown refused to make a statement. The Maryland Company is capitalized at $1,000,000 with $1,000,000 of 5 per cent. bonds. The Pittsburg & Allegheny Company has $1,500,000 of stock and $1,200,000 of 5 per cent. bonds. The Erie Telephone & Telegraph Company is incorporated under the laws of New York, but is controlled by the New England people, the main office being in Lowell, Mass.

After several weeks' negotiations between the local company and the Southern Bell Company, West Point, Ga., is at last assured of first-class telephone service. For the past few months the telephone service has been unsatisfactory on account of the poor boxes. But before December 1 the best system that can be had will be established there. The local company will be reorganized under the name of the West Point Telephone & Electric Company, and Mr. J. Smith Lanier will be president and general manager. It will rent from the Bell Company all the telephones, using the new kind, that requires no ringing and the battery being operated by the central office. Nearly 150 telephones have been contracted for under the new system. The new central office will have direct connection with the long-distance telephone.

Edward Barkalow of the Kokomo, Ind., Telephone & Electric Company has secured a patent on a new telephone transmitter that amplifies sound. A test of 50 miles distance has been made by a whispered message at the receiving end, and the volume of sound was increased to the tone of an ordinary conversation at the other end of the line. The merit of the invention lies in the perfect privacy of the conversation.

The People's Mutual Telephone Company, incorporated in 1895, is now making active preparations to install an opposition telephone system in San Francisco, Cal. A thorough canvass of all telephone users is being made with gratifying results. The new company expects to be in operation within a year and a half. Business men will welcome any relief from the exorbitant charges and poor service now in vogue.

A new telephone line, starting at Upper Page Brook, and running directly to Binghamton, N. Y., is in the course of construction. When completed, this will make a continuous line from Greene to Binghamton.

One hundred and thirty-six telephones are used at La Grande, Ore.

A local telephone exchange was recently put in at Harrington, Wash.

TELEPHONE INCORPORATIONS.

The Continental Telephone Construction Company, Chicago, Ill. Capital stock, $2,500. Incorporators: Henry Shafer S. W. Moon, Frank L. Bills.

GENERAL ELECTRICAL NEWS.

Lighting.

Appleton, Wis.—The Fox River Valley Electric Railway Company will construct a temporary electric light plant here and in the spring erect a permanent one.

Arkadelphia, Ark.—Capt. Albert Moore and his associates were lately granted a fifty-year franchise by the city council for putting in an electric light plant. They have to commence the work in sixty days, or the franchise will be void.

Ashland, Ky.—The Ohio Valley Electric Company will spend about $200,000 in enlarging its electric light plant.

Baldwin, Wis.—E. J. Cave has purchased the franchise and plant of the Baldwin Electric Light Company and will improve the system.

Beloit, Kan.—The electric light plant at the State Industrial School was recently destroyed by fire. The loss is estimated at $15,000.

Big Rapids, Mich.—This city will receive bids until December 3 for the furnishing of not less than 50 street lights. Bids are to be made for 1,200 and 2,000 candle power lights. Address city clerk.

Centralia, Ill.—The Centralia Light & Power Company is arranging to put in a third dynamo in its plant in order to meet the demand for incandescent lights.

Columbiana, O.—H. O. Brown contemplates erecting an electric light plant at this place.

Conway, Ark.—At a recent meeting of the town council an ordinance was adopted to lay off the town into one improvement district for the purpose of purchasing, owning and operating an electric light plant for lighting the streets and furnishing lights to individuals.

Dayton, O.—The car shops are putting in an extensive electric plant of its own at an expenditure of over $60,000. The company expects a contract shortly for 2,400 cars.

East Grand Forks, Minn.—The city council lately decided to establish an electric light plant and a water works system.

Herkimer, N. Y.—The contract for wiring the new St. Francis de Sales Church for electricity has been awarded to David Cronin of Syracuse.

London, O.—It was voted a short time ago to issue $5,000 worth of bonds for the purpose of purchasing new machinery for the electric light plant.

Manhattan Kan.—C. P. Demey has acquired the Manhattan electric light plant, and will extend and develop it.

Nashville, Tenn.—G. F. Bron of Philadelphia and T. Taylor of this city have submitted a proposition to the council to construct and operate an electric lighting plant for the city. An appropriation of $150,000 was authorized at a recent election for a new plant.

Neponset, Ill.—The citizens of this place are agitating the electric light question.

New London, Conn.—This city will remove all the naphtha lamps and replace them with electric lights.

Pitman Grove, N. J.—The plant of the Gloucester County Electric Light Company was recently damaged by fire.

Pratt City, Ala.—This city is considering the question of erecting an electric light plant.

Providence, R. I.—The work of placing the wires of the Narragansett Electric Lighting Company underground in the district bounded by the Providence River, Jackson, Pine and Washington streets, commenced about two years ago, is nearing completion, and in six weeks it is very probable that the highways in the area specified will be clear of wires and poles.

Red Lion, Pa.—The electric light plant here burned recently entailing a loss of $5,000.

Renovo, Pa.—There is talk of this place having electric lights before long.

Saratoga, Wyo.—It is proposed to erect an electric light plant on the Platte River. A. J. Doggett, mayor.

Selin's Grove, Pa.—At a special election in this borough the authorities were authorized to build an electric light plant at a cost of not more than $10,000.

Shreveport, La.—Bids will be received until December 1 for the electric lighting of this city for a period of five years from June 1, 1901. Address H. B. Murff.

Victoria, Tex.—The electric light works and other enterprises here are experiencing difficulty in replenishing depleted fuel supplies, and the wood yards are getting very short.

Wichita Falls, Tex.—An electric light plant is projected for this place.

Woodburn, Ore.—This place is to have an electric light plant; a 30-year franchise was recently granted to A. B. Kurtz by the council.

Street Railways.

Akron, O.—T. L. Childs has filed an application with the Stark County Commissioners for a franchise permitting the Canton & Akron Eectric Railway Company to run its line through Stark County from Canton northward.

Benton Harbor, Mich.—Plans for the construction of an electric railway through the center of the Michigan fruit belt are now being made by a number of Chicago capitalists headed by J. J. Sturm.

Bluffton, Ind.—J. M. Gore, promoter of the Indiana & Ohio Electric Railway Company, proposes to build a line between here and Muncie, Ind.

East McKeesport, Pa.—The East McKeesport Railway Company will erect a power house on property recently purchased between here and Wilmerding.

Goshen, Ind.—J. J. Burns is president of the Goshen, Wawaka & Southern Electric Railway Company, recently formed to build an electric line from this city to Wawaka.

Grand Rapids, Mich.—According to the statements of its promoters the electric railroad from this city to Ionia by way of Lowell and Saranac is now assured and the capital necessary to build and equip the road complete is not only in sight, but is secured by contracts.

Hackensack, N. J.—The Hoboken & Paterson Traction Company will pay $35,000 of the orignal cost of the bridge over the Hackensack River for permission to run its trolley cars over it. The rest of the expense will be borne by Bergen County.

Harrisburg, Pa.—The much talked-of trolley line project between this city and Lingiestown is now an assured fact. An organization has been effected by the election of president, Dr. C. H. Smith, Linglestown; secretary, George W. McIlhenny, Harrisburg, and treasurer J. G. Diffenderfer, Steelton.

Lyons, N. Y.—Chas. Van Voorhis and other members of the Cuyler-Morgan Railroad Syndicate have been inspecting the plans and routes for the proposed electric railway between this village and Sodus Point.

Omaha. Neb.—The Omaha & Fremont Railway Company has lately been incorporated for $750,000 by I Noyes, president; J. S. Knox of Omaha, secretary, and others. The new road will run between Omaha and Fremont, and the motive power will be electricity or compressed air.

Owosso, Mich.—J. D. H. Ralph, president of the Owosso & Corunna Electric Company, has sold the electric line which runs between the two towns to parties in Philadelphia. The new owners will extend the line and make many improvements.

Peekskill, N. Y.—A mortgage for $750,000 was filed a short time ago in the Register's office of Westchester County by the Peekskill Lighting & Railroad Company to enable it to make extensions on its lines in the northern part of the county and Connecticut.

Philadelphia, Pa.—The League Island Navy Yard will shortly enjoy the advantages of a trolley line. Major Wolcott, civil engineer at the yard, is superintending the building of the line and hopes to have it in operation by Thanksgiving Day.—The Inland Trolley Company is preparing to begin work on its line from Chestnut Hill northward toward Ft. Washton and North Wales.

Rockford, Ill.—President W. W. Clough of the Rockford, Beloit & Janesville Electric Railway Company states that the northern line will be constructed, equipped and in operation by July 1.—The Rockford Railway Light & Power Company expects to build the Belvidere line in early summer if the necessary franchises are secured.

Rushville, Ind.—A corps of engineers under the charge of Mr. Horton recently completed a preliminary survey of the route of the proposed Indianapolis, Morristown & Rushville Electric Railway.

Santa Fe, N. M.—The Colorado promoters of the Santa Fe Electric Railway are figuring on the building of an electric railway line to the Cochiti. A prospectus of the resources of that district is being prepared with that purpose in view.

Sedalia, Mo.—A Sedalia capitalist proposes to build an electric road east and west out of Nevada.

Toledo, O.—This city will soon be connected with Chicago by an electric railroad. Michigan and Indiana capitalists have incorporated a company for that purpose to be known as the Chicago & Toledo Railway Company. They will build a line through the counties of Newton, Jasper, Pulaski, Fulton, Kosciusko, Whitney and Noble. J. A. Hamilton of White Cloud, Mich., is at the head of the company.

Westfield, N. J.—W. G. Peckham is interested in the proposed trolley road between this place and Springfield.

Company Matters.

Chicago, Ill.—The Leecoll Storage Battery Company's number of directors has been changed from four to five.

Milwaukee, Wis.—Walter Cary recently said that the Milwaukee Electric Company, of which he is vice-president, expects to build a $40,000 factory as soon as a suitable location could be found.

Warren, O.—The Warren Electric & Specialty Company recently voted to increase its capital stock from $100,000 to $200,000.

Manufacturing.

Birmingham, Ala.—The Boykin-Bullock-McCall-McDonnell Electric Company has recently been organized with a capital of $40,000 for the purpose of manufacturing and dealing in electrical supplies. F. M. Boykin, E. W. Bullock, E. L. McCall, I. F. McDonnell and H. H. Peevey are at the head of the firm.

New York City.—The Hungerford Electric & Manufacturing Company has been formed lately to do a general electric and manufacturing business. Among those interested are: J. S. Honeycombe, A. W. Rose, P. Dwight, E. B. Merrill, S. D. Maynard, all of New York City. The capital of the concern is $1,500,000.

Oriental, N. C.—P. J. Delamon of this place wants correspondence with manufacturers of electrical machinery, etc.

Power and Transmission.

Ashland, Pa.—Plans for the building of a new power plant are being considered by the Schuylkill Traction Company.

Carthage, N. Y.—P. J. Corcoran and John E. Strickland have purchased two water powers on Beaver River capable of developing 2,500 horse power. Already work has begun toward developing these powers, and by another year Beaver River will be lighting this city.

Chattanooga, Tenn.—The Rapid Transit Company will treble the capacity of its electric power plant.

Fruitvale, Cal.—The Fruitvale Light, Power & Heat Company has been formed for the purpose of manufacturing and transmitting gas and electricity for lighting and heating purposes. The capital stock of the corporation is fixed at $100,000, of which J. C. Hammell, A. N. Frost, Charles H. Fehnemann, J. H. W. Riley, P. H. Blake, B. Fehnemann, L. Battles and Amy G. G. Fehnemann are the stockholders.

Automobiles.

New York City.—The C. J. Downing & Co. was lately organized here by C. J. Downing, V. B. Rice and Carrie M. Downing, for the purpose of dealing in bicycles and automobiles, with a capital stock of $5,000.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The annual meeting of the Metropolitan Street Railway Company will be held in this city December 3.

It is reported from Worcester, Mass., that a consolidation of all the street railways centering there has been effected.

The Kings County (N.Y.) Electric Light and Power Company will issue on November 21, $520,000 new stock at par, making the total $2,500,000.

A strike of the employes of the Southwestern Telegraph and Telephone Company, part of the Bell system, is said so be spreading through Texas and Arkansas.

The regular quarterly dividend (No. 22) will be paid on the common capital stock of the American Graphophone Company on December 15 to stockholders of record December 1.

Advices from Allentown, Pa., state that the Lehigh Valley Traction Company has bought the Allentown and Slatington trolley lines, 21 miles long, and the Slate Belt Line, 17 miles long.

The gross earnings of the Cleveland Electric Railway for the month of October were $185,000. The gross receipts are $34,200 in excess of October, 1898, and $45,000 in excess of October, 1899.

A dispatch from Chester, Pa., states that the Philadelphia & Delaware Railway and the Prospect Street Railway companies have consolidated under the name of the Philadelphia and Chester Railway Company.

The Buffalo and Niagara Falls Electric Light and Power Company will hold a meeting on November 26 at the office of the company in Buffalo for the purpose of voting on the proposition to increase the capital stock of the concern from $200,000 to $500,000.

President Charles J. Glidden, of the Erie Telephone system says that there is not a word of truth in the dispatch sent out from Baltimore that the Erie Company had purchased the independent telephone properties at Baltimore, Pittsburgh, and at other points.

The annual report of the Ballston (N. Y.) Terminal Railroad Company for the year ended June 30 last shows the gross earnings to be $14,243; operating expenses $13,650; net earnings, $537. The report of the road for the September quarter shows gross earnings, $5,328; operating expenses, $5,230, net earnings, $98.

The Western Electric Company has executed a trust deed to the Chicago Title and Trust Company upon 225,000 square feet of land at West Polk street, Chicago, and the river, to secure a bond issue of $500,000, payable in five years, and bearing 4½ per cent. interest. The interest is payable at the Bank of New York, the National Banking Association of New York.

The Edison Electric Illuminating Company of Boston has filed with the commissioner of corporations the following certificate of condition of September 30, 1900. Assets: Land and water power, $309,358; buildings, $881,214; machinery, $1,856,083; debts receivable, $356,341; stock in process, $90,765; miscellaneous, $2,108,532; total, $5,602,293; Liabilities: capital stock, $4,310,500; debts, $369,950; balance profit and loss, $446,343; reserve for depreciation, 475,500; total, $5,602,293.

United States production of copper (long tons) for October, 1900, aggregated 23,345 tons compared with 21,086 tons for the previous month and 23,980 tons, October, 1899. For ten months, 223,387 tons compared with 215,201 for the corresponding period in 1899, 195,940 tons in 1898, 176,398 tons in 1897 and 169,910 tons in 1896. Exports of copper from the United States (long tons) for October, 1900, aggregated 12,682 tons compared with 10,425 the previous month, and 11,360 tons October, 1899. For ten months, 138,881 tons compared with 93,453 tons the corresponding period in 1899, 117,152 tons in 1898, 109,334 tons in 1897 and 100,591 tons in 1896.

The Boston "News Bureau," says: "The statement of the General Electric Company for the seven months ended August 31 shows net earnings after all expenses, interest charges and preferred stock dividends, of $3,219,978, which is equivalent to 17½ per cent. on $18,276,000 common stock then outstanding. The sales of the company for these seven months amounted to $14,803,383, confirming our previous statements to the effect that the company was doing a gross business of $2,000,000 a month. The sales for the fiscal year ended January 31, 1900, amounted to $22,379,463. The manufacturing profit for the seven months was about 20 per cent., which, added to the income from the company's investments, should bring the earnings of the current year to an amount equivalent to between 30 per cent. and 35 per cent. on the common stock. Earnings last year showed 27 per cent."

The General Carriage Company announces that it has just completed a traffic arrangement with the Westcott Express Company by which its cabs are hereafter to serve the Grand Central Depot and elsewhere in this city where Westcott express cabs are stationed. The Carriage Company reports that it is steadily increasing the number of its cabs and the efficiency of service. In the past three months it has installed a service in connection with the Baltimore and Ohio Railroad and is now running a complete line of cabs of various patterns. It is officially stated that the earnings of the company are demonstrating that the public will patronize liberally a cheap but well conducted cab service.

A director of the General Electric Company is quoted as follows: "It is determined by the management to continue the process of drastic 'writing off' adopted in previous years, but that, notwithstanding this, the chances are that the profit and loss surplus at the end of the year will stand somewhere near $6,000,000, against about $2,400,000 on January last. It must be remembered that this is in every sense an actual surplus, being represented by cash assets in working capital. By the replacement of debentures with five-sixths of their par value in common stock, the company creates an additional surplus of some hundreds of thousands of dollars by writing down its capital stock that amount. It will then have no debts, and working capital for every dollar of its capital stock, to say nothing of an earning capacity of about 30 per cent. on the stock."

EDITORIAL NOTES.

The Unwholesomeness of New York's Water.

About this time every year numerous complaints reach the Health Department in this city, regarding the color and taste of the water furnished the inhabitants by the authorities. Last year the matter received considerable attention at the hands of the Board of Health and the daily papers, and although Dr. Charles F. Roberts, sanitary superintendent of the Health Department, recommended that a system of filtration be adopted, nothing was done other than to blow off dead ends and hydrants throughout the boroughs of Manhattan and Bronx.

This important matter which affects the well being of some 2,000,000 people has again only recently, been brought to the attention of the authorities through the condition of the water, which is even worse than it has been at any time previous. Dr. Roberts in an interview refers to the condition of the supply as follows:

"From October until the middle of December the water has been turbid for years, and it will continue to be so until the city puts in a filtering plant. Croton Lake has been a receiving basin for more than half a century. Its bottom is covered with a thick deposit, derived partly from organic and partly from inorganic sources. Portions of this deposit are carried by the water and distributed through the mains of the city.

"However offensive and disagreeable the water may be, there is no typhoid in it. This is shown by the analysis, and by the fact that no increase in the number of typhoid cases has been reported.

"What effect the impure water has upon stomach and intestinal troubles and upon the mortality among children is another matter. Diarrhœa, gastritis and entritis are caused and intensified by the use of water of this character.

"I have recommended that a system of filtering the entire supply of the city be established. Other large cities filter their water, and their statistics show a lower death rate and reduced number of typhoid cases. London uses a sand filtration system. We would probably obtain better results, at less cost, if a mechanical filter were used, as it requires less space."

Last year Dr. Roberts made practically the same recommendation. and as was to have been expected no action was taken by the city authorities, owing to the expense such a filtration plant would involve. At that time we called attention in these columns to a method of purifying water in use at Saint Maur near Paris, France, which might possibly be adopted to advantage in connection with the Croton supply. This system, which consisted in passing air that has been subjected to the action of a high-tension electric current through the body of water to be purified, is comparatively inexpensive and yet accomplishes most thoroughly the object intended, namely, sterilization.

According to statistics the cost of purifying a cubic yard of water by this method is .028 cent. With this figure as a basis and assuming the amount of water consumed daily in the boroughs of Manhattan and Bronx, amounts to about 250,000,000 gallons (which it does), the daily expense to the city for purifying this body of water would be in round numbers $335. In a year this would amount to $122,275, which is certainly little enough to pay for good, wholesome water, especially when it is recalled that the annual cost of maintenance of the Water Supply Department of this city amounts to over $1,500,000.

It might be well for the authorities to examinine into this French system of water purification, especially in view of the fact that some 20,000,000 gallons of the water which is consumed in Paris is daily treated by this process.

* * *

Preliminary Trial of Electricity on the Elevated Roads.

After a patient wait of several years, it would seem as though the non complaining citizens of New York City would shortly be able to journey from their offices to their residences uptown without the waste of an enormous amount of time, and last but not least in comparative comfort. The long-promised third-rail system for the elevated roads is beginning to materialize, a stretch of track along Second avenue from Sixty-fifth to Ninety-fourth street having been equipped with this method of propulsion.

With a view to testing the working of the apparatus an experimental train was run over the new section on November 22 and attracted no little attention. The train consisted of two motor cars and four trailers, the former being

located one at each end of the train. Everything was new and up-to-date. The cars are the same length as those now in use, though broader and raised more from the tracks. They weigh about 16 tons apiece. The motor cars, which are provided with four 150 horse-power electric motors each, rest on heavy steel frames and weigh about 35 tons. The current is taken from the third-rail by means of iron contact shoes in the ordinary manner. One commendable feature to be noticed on the section just completed is that the third-rail is encased between planks set on edge to prevent any one coming in contact with the live rail.

A feature of this system is that the operating mechanism is controlled from the cab in the front motor car. The method is very similar to the ordinary system of hand control, but much simpler than anything hitherto tried. The locomotives would seem a combination of those used on the Baltimore & Ohio road and those on the London Underground.

In the trial runs last week the train consisting, as already stated, of six cars, obtained an average speed of about 34 miles an hour. Referring to the change of motive power, Mr. Hugh Hazleton, assistant electrical engineer of the road, is reported as saying:

"The change from steam to electricity will be made gradually. Work on the power station at Seventy-fourth and Seventy-fifth streets and East River is under way, and we expect that it and the seven sub-stations along the line, from which the current will be distributed to the rails, will be completed in three months.

"Owing to an electrically driven air compressor and the air brake apparatus, the stops and starts are smoothly executed. The electric trains will be first introduced on the Second avenue line. We expect to gain at least ten minutes in running trains from the Battery to 155th street on the Sixth avenue line. With this system of propulsion we obtain four times the horse power provided by the ordinary steam engine."

The general adoption of electricity on the elevated roads will much decrease the time of travel between the Battery and Harlem. As stated above a speed of thirty-four miles an hour could be attained instead of eleven or twelve as at present. In view of this fact it is to be hoped that the Manhattan Elevated Railway Company will make every effort to complete the change as soon as possible.

* * *

The Mica Production of this Country.

The report of the United States Geological Survey, covering the mineral resources of this country for the calendar year of 1899, shows, among interesting data, that the mica production in 1899 consisted of 108,570 pounds of sheet mica valued at $70,587 as compared with 129,520 pounds valued at $103,534 in 1898; in addition to this there was a production of 1,505 short tons of scrap mica, worth $30,878 as against 3,999 short tons at $27,-564 in 1898. These figures show two things: first, in both production and value of sheet mica during 1899 as compared with 1898 of 20,950 pounds, and $32,947 respectively; second, a decrease in the quantity of scrap mica of 2,494 short tons, or of over 60 per cent., with an increase in value of $3,314, or 12 per cent.

The decrease in domestic production is ascribed in large measure to the very large importations of foreign mica during the past year. This may reasonably be supposed to be the case, if we compare the importations for the last five years, ending June 30 of each year, as follows: 1895, 820,982 pounds, $127,515; 1896, 1,264,066 pounds, $214,991; 1897, 881,510 pounds, $187,845; 1898, 625,083 pounds, $94,294; 1899, 259,228 pounds, $1,616,397.

Taking the report for the calendar year of 1899 it is seen that the total importation of mica manufactured was 1,709,839 pounds, which was nearly double that of the year preceding and the total value was greater than any ever before recorded.

The reason for the increased demand for mica is easily to be found in the development of the use of electricity during the past few years, which has created a demand for mica as an insulating material, and much of the small-sized mica, which was formerly of little value, if not altogether unsalable, now finds a market among electrical manufacturers. Part of this is reported with the sheet mica product, and as it sells for much less than the larger sizes, which are used in the manufacture of heating stoves, lamp chimneys, etc., it has the effect of making an apparent decline in values. On the other hand, part of the small-sized sheet mica used for electrical purposes is reported as scrap, and in this case causes an augmented value. As an instance, in 1896 the value of scrap mica produced and reported as such was only $1,750; in 1897 it had increased to $14,452; in 1898, $27,-564, and as already stated, to $30,878 in 1899.

From the year 1880 up to and including the year 1892 the returns covering the production of scrap and sheet mica in the United States were not reported separate.

When the Dingley bill was enacted it carried in it a provision whereby mica has two specific classifications and rates of duty, one as "unmanufactured," dutiable at six cents per pound and twenty per centum ad valorem, the other as "cut or trimmed," at twelve cents per pound and twenty per centum ad valorem: and the imports for those years as specified, show that, in 1897, and prior to the enactment of the law on July 24, the quantity of both classes combined was 656,118 pounds at $140,353; after that date, unmanufactured, 66,821 pounds at $10,-981 and cut or trimmed 226,771 pounds at $41,068. In 1898 the quantity of unmanufactured was 877,930 pounds at $115,930, and of cut or trimmed, 78,567 pounds at $34,152; and in 1899, 1,709,839 pounds unmanufactured at $233,-446, and 67,293 pounds at $42,538 of cut or trimmed. It will thus be seen that the importation is rapidly on the increase.

ONE of the advantages derived from the use of Marconi telegraphic outfits on boats crossing the English Channel is that notice can be given to connecting railways regarding the number of passengers for whom accommodations are required. In such instances the proper information is transmitted to the port at which the steamer is about to arrive. But a Belgian vessel demonstrated another interesting possibility the other day. She left Ostend for Dover in an exceptionally heavy gale, although she carried a number of Government officials desirous of witnessing a test of the system. The two ports are over seventy miles apart. Yet until within a few miles of Dover the steamer continued to report back to Ostend her progress and safety, besides dispatching numerous complimentary messages. In case a boat should be disabled, it would be even more desirable to maintain communication with her owners than if unharmed. The line to which this particular vessel belongs will now equip its whole fleet with Marconi apparatus.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

THE 148th meeting of the American Institute of Electrical Engineers was held at 12 West 31st street, New York, on the evening of November 23. A paper was presented by Mr. B. A. Behrend on "The Mechanical Forces in Dynamos Caused by Magnetic Attraction." The plant of the St. Croix Power Company of Wisconsin was also ably dealt with in a paper by Mr. Henry Floy.

THE Rensselaer Polytechnic Institute at Troy, N. Y., which is about to give special and thorough courses in electrical engineering, is having fitted up a new electrical laboratory. The dynamos, transformers and other electrical apparatus have already arrived. Large sums for equipping this laboratory have been donated by local alumni.

THE first electric cars ever operated in Honolulu began running to Pacific Heights on November 12. Work on electric lines throughout the city has begun.

THE question is being agitated at Austin, Tex., for an electric fire alarm system for that city. The telephone is used at present, but at times it causes a delay, and is not as quick as an electrical service. It is said that one of the aldermen will introduce an ordinance at the next meeting of the council providing for a first class electric fire alarm.

THE Havana Electric Railway Company will have its new line and the reconstruction of the old completed by March next. All the important contracts have been let.

ADVICES from London state that the General Post Office is said to have taken over the Marconi system of wireless telegraphy. If this should prove so nobody but the Government will have the legal right to operate that method. The statement is not confirmed yet, but an expert commisson of the Postal Department is preparing a report on the question of its adoption. Whether this will result in a revolution in telegraphy there, or is merely a Governmental safeguard, remains to be seen.

THE new escalator of the Manhattan Elevated Railway, at the corner of Sixth avenue and Twenty-third street in this city, was put into operation November 23. The cost of the plant is estimated at about $15,000. The stairway will carry more than a hundred people at a time.

THE Cahill electrical typewriter is the invention of a Washington, D. C., man, Dr. Thaddeus Cahill, who has applied electricity to impel the mechanism. A magnet is placed in the machine to impel the type bars, space mechanism and all other moving parts, and the finger of the operator merely designates which letter shall be printed, touches it lightly, the circuit closes and electricity performs the work. No matter how hard a key may be struck the impression is always uniform. The

Digitized by Google

machine is also equipped with a rheostat, by means of which a stronger current may be secured for manifolding.

A NUMBER of motors will probably be placed in use by the New York Central Railway shortly, as an experiment in the Park avenue tunnel in this city. President Callaway is much interested in the matter, and it is due to the agitation against the nuisance of steam engines running through the tunnel to the great annoyance of residents along the line that the change is being made.

THE Onondaga Dynamo Company and the Straight Mine Company of Syracuse, N. Y., will have electrical exhibits at the Pan-American Exposition. The two companies will unite in operating the generators, dynamos and other machinery necessary for the running of the electrical display in the court of the Machinery Building and in the illumination of the fountain.

A PLAN is well under way to establish in Yonkers, N. Y., a new department to be known as a Bureau of Electricity. Already sub-committees have been appointed by the police and fire boards looking toward an improvement which, it is asserted, has been found to be an urgent necessity.

FROM Paris comes the statement that one of the most frequent uses to which the telephone is put by French country subscribers is that of an alarm to wake them in the morning. Those who wish to be aroused at a given hour have only to advise the telephone administration the night before of the hour at which they wish to arise.

THE Penn Gas Coal Company at Greensburg, Pa., took out its first coal a short time ago at its Penn mines under the new electric haulage system. A powerful electric motor takes the place of the old engine formerly employed to bring the coal from the mines.

NINE Chinamen, living in Mott and Pell streets of this city, were arrested last week on the complaint of the Edison Electric Illuminating Company. They were charged with tampering with the electric meters in their stores so that they would not register the amount of electricity used.

A CORRESPONDENT signing himself "South Africa" writes to the London "Times" as follows: "I can give you another illustration of the way in which the indifference of the British manufacturer drives trade into foreign hands. I recently applied to a maker in London for quotation for some thousands of wood boxes, specifying the size, and the nature and weight of the contents they were to carry. The British manufacturer asked for particulars as to the thickness of the wood and declined to quote without this information. While obtaining the necessary details from abroad, I at the same time sent the inquiry to America, and received a reply by return mail, quoting prices for boxes and estimated strength to carry the contents specified, although stating that the thickness should have been given. The result is that America will probably get the order. I see the two rivals sitting side by side at a dinner table. The Yankee at once 'goes for' the repast and satisfies his needs. The Britisher finds himself short of a knife or a spoon, calls for the missing article and will not commence his meal until he gets it, and when at last it comes the dinner is all consumed. Surely the British manufacturer must be losing his appetite for trade."

THE Nickle Copper Company of Ontario has recently been experimenting with a new process of nickle and copper extraction. The process is the invention of Mr. H. A. Frasch, and it is said to be very successful. As applied to the Sudbury copper-nickle matte, the process consists, says the "Engineering and Mining Journal," in the electrolysis of a brine solution in such a manner that, while the sodium ions are set free at the cathodes with the formation there of caustic soda, the chlorine ions are liberated in the anode section containing the matte and immediately form a chloride solution of the metals present.

A NEW method for hardening and increasing the life of storage battery plates has just been patented. It consists in dipping the plates alternately in acidulated water and a dilute solution of pyridin, which is a complex chemical substance derived synthetically from coal-tar residues. In the pyridin solution is a small quantity of alcohol, and it is asserted that the combination of all the agencies concerned results in greatly strengthening the plate mechanically and also by highly oxidizing the plate, in making it of considerably higher capacity than it would be without this treatment.

HEAVY cars, each holding sixty passengers, traveled easily thirty-seven miles in one hour over the Albany and Hudson Electric Railway at the formal opening on November 22. The run was from Hudson to Rensselaer and return. The distance between those two places is thirty-seven miles. Power is obtained from the Stuyvesant Falls for running the trains and will also be used for lighting towns and villages along the line and for furnishing power. The power part of the plant has been in successful operation, and the current already is used in lighting the towns of Hudson and Rensselaer. The road runs through a hilly country, but the cars mount the grades without apparent trouble. It is generally believed that this is the beginning of an electric line eventually to extend from Albany to New York.

A LARGE number of supporters for cables have been devised, the conditions necessary to be fulfilled by a successful appliance of this sort being so difficult that great trouble has been encountered in finding one that would meet them. At one time tarred ratline, or small hemp yarn, was used, the yarn being spun from a contrivance made for the purpose about the support wire and the cable so that the latter hung in a great number of loops of the soft yarn from the former. The difficulty with this method was that in the course of time the ratline would naturally rot and allow the cable to fall. Metallic slings of various kinds have been made, and while some of them have been successful, most of them either grip the cable so tightly as to weaken or injure it, or else hold it so loosely as to let it slip down hill on inclined lines or toward the lowest point of the sag between poles. A new type of cable-clip grasps the cable by means of a soft metal band encircling it and tightened by the weight of the cable itself, much in the same way as the buckle of a patent shawl strap is worked.

"Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 3.

THE ELECTRICAL MEASUREMENTS.

We employ electricity in a thousand different ways and for a thousand different purposes. It has become a commercial necessity. We buy and sell it, light our homes, run cars, transmit messages, supply power for mills, in fact use it in innumerable ways, and to do this we must be able to measure it so that we can employ its services, buy or sell it with some degree of accuracy. Although electricity has an existence, yet we cannot weigh it for it has no weight, neither can we measure it by quarts or gallons, for it does not occupy space, nor yet by sound, for it cannot be heard, nor by a rule, for it has not form, but we can measure it by its power of doing work. Now understand this clearly. Suppose we have a certain amount of work to perform. We know we can do it by electrical energy and that to do double that amount of work it will just take double the amount of electrical energy, so we base our measurements on what it will accomplish and deduce a rule that is just as accurate electrically as that we know that two and two make four and that twice two can never make anything but four.

The three measurements in electricity which are the most important are: The volt, the ampere and the ohm.

We will explain these three terms in the order given and endeavor to compare them with something or some laws with which we are all familiar so that they may be the better understood.

The volt is the practical unit of measurement of electrical pressure or force.

In the boiler of a steam engine the steam has a certain force registered by the steam gauge which indicates the pounds pressure per square inch. Now if there be a pipe attached to the boiler and the steam is allowed to escape it will be forced out by the pressure in the boiler, and if some obstacle be placed in the way it will be forced to one side because the energy will be exerted upon it. Just so in electricity, we have a force or pressure of the current dependent upon its source and this pressure we call voltage, and we can measure it in volts or force units because it has the power of doing work just as steam has when it is under pressure and has force.

Take as another illustration: Suppose there be a reservoir of water on a high elevation and discharge pipes connected to it; the force or pressure of water at the point of discharge will be dependent upon the weight of water above that point, or in other words, the elevation of the reservoir above the point of discharge can be registered by pounds per square inch. Of course it makes no difference whether the discharge pipe be large or small, the pressure of water will be the same, that is, the pressure of water at the discharge point will not depend upon the size of the pipe or the amount of water it contains, but, as we said before, depends entirely upon the elevation of the water in the reservoir. Now just so in electricity,

Digitized by Google

do not conflict the amount of current with the pressure, for the voltage is not dependent upon the amount of current but upon the force or pressure of it. As pounds per square inch indicate the pressure of the water in the pipe regardless of the amount it contains so voltage in electricity represents the force or pressure of the electricity regardless of the amount of current or flow.

The ampere is the practical unit of measurement of the rate of flow of electricity.

Take again our example of the reservoir. If the discharge pipe be one inch in diameter and is opened to the free flow of water the rate of discharge would be calculated by gallons per minute. Now suppose that the pipe be two inches in diameter, then the rate of flow would be a great deal more. The water is forced through the pipe by the pressure, but it is discharging at a certain rate dependent upon the size of the pipe and the pressure, so we now have another measurement to take into consideration, which is the quantity of water discharging, or, in other words, the rate of flow. Just as the pressure forces the water to flow at a certain rate and the rate is measured by gallons per minute, so in electricity the voltage forces the current to flow at a certain rate, and that rate is measured by amperes of which one ampere is the unit.

The ohm: Again resorting to our example of the reservoir of water, you know that much more water flows through the two-inch pipe than there will through the one-inch pipe, and why? Because there is less resistance to the flow. So you see there is something that prevents all the water flowing away at once, and that is, it is not permitted to do so on account of the size of the pipe, which is the resistance offered to it. So we come to another condition that we must take into consideration, and that is the resistance offered to its rate of flow. In electricity we have a corresponding measurement to be considered, and that is the resistance offered to the flow of current. This is measured in ohms of which one ohm is the unit.

In our example of the reservoir we measured the pressure by pounds per square inch, the rate of flow by gallons per minute and the resistance to that rate of flow calculated by the diameter or size of pipe which is used to discharge, also we have our three measurements in electricity—the pressure or force measured by volts, the rate of flow by amperes, and the resistance to the rate of flow by ohms. As you know water has substance and weight and therefore occupies space, but electricity has neither substance nor weight and does not occupy any space, consequently we must now drop our comparison which we used for the sake of explanation and apply the electrical measurements.

One volt is that amount of electrical pressure or force which will cause one ampere of current to flow over the resistance of one ohm.

One ampere is the amount of current that will flow over the resistance of one ohm when forced by the pressure of one volt.

One ohm is the amount of resistance that will permit the flow of only one ampere when forced by the pressure of one volt.

When water is forced through a pipe under pressure from a reservoir or other source, the stream of water which flows is proportional to the pressure divided by the resistance which the pipe presents to the flow of the water. In just the same way when a current flows through a wire under the pressure from a dynamo or other source of electricity, the current which flows is equal to the pressure or force divided by the resistance of the circuit. This relation between the three measurements, pressure, current and resistance, is called Ohm's Law and is often written $C = \frac{E}{R}$, where C stands for current, E for pressure and R for resistance.

Take as a demonstration of this so that it may be more clearly understood: 1 volt will force 1 ampere over the resistance of 1 ohm, then 8 volts would force 8 amperes over the resistance of 1 ohm, but 8 volts would only force 4 amperes over the resistance of 2 ohms; 8 then is the number of volts of electrical pressure required to force 4 amperes of current over the resistance of 2 ohms. Now

$4 = 8 \div 2$ and $8 = 4 \times 2$ and $2 = 8 \div 4$.
8 represents the pressure or force,
4 represents the current, and
2 represents the resistance.

To find the voltage in a circuit multiply the current by the resistance.

To find the current flowing in a circuit divide the pressure by the resistance.

To find the resistance of a circuit divide the pressure or voltage by the current.

Wherever you have two of the measurements of Ohm's Law known you can easily find the third, for $C = E \div R$, $E = R \times C$, $R = E \div C$.

The electrical power of doing work is measured by watts, of which one watt is the unit. One watt is the amount of work accomplished by one ampere of current when forced by the pressure of one volt.

One volt and one ampere will do one watt of work. Two volts and one ampere would do two watts of work. Two volts and two amperes would do four watts of work, etc.

So to find the watts multiply the volts by the amperes; 746 watts is equivalent to a horse power, which is that amount of energy required to lift 33,000 pounds one foot in one minute. Now to find the horse-power of an electric current, multiply the volts by the amperes and divide by 746.

SOME EXAMPLES TO WORK.

Find the resistance of a circuit over which 10 amperes are flowing at a pressure of 50 volts?

Find the voltage required to force 5 amperes of current over a resistance of 20 ohms?

Find the amperes flowing in a circuit of 20 ohms resistance with a pressure of 100 volts?

Find the watt capacity of an electrical machine which is capable of producing 500 amperes at a pressure of 110 volts? What would be the theoretical horse-power required to operate this machine when carrying full load? The answers to these examples will appear in the next issue.

Article No. 4 will be entitled Primary Batteries (current produced by chemical action).

Setting Diamonds by Electricity.

George Anderson, a Scotchman, has recently patented in this country a method of setting diamonds or other precious stones by electricity. A hole is first drilled nearly through the metal in which the stone is to be set: the latter is placed in this hole; the metal is brought to a welding heat by electricity, and the hole behind the stone is closed. The latter is now completely surrounded by a mass of the metal setting. The latter is then ground away so as to expose the stone, any desired form of setting being readily obtained.

THE PARIS EXPOSITION OF 1900.*

BY CARL HERING,
President of the American Institute of Electrical Engineers.

A large international exhibition, like the one about to close, may be judged from two standpoints. For commercial reasons a necessary feature is its general attractiveness, that is, its beauty, architecturally as well as in the arrangement of the grounds and in the decorations, its proper combination of instruction and entertainment, and its purely entertaining features. On the other hand such an exhibition should be a representation of what is called the state of the art in the various industries, and to a certain extent at least, show the relative importance of competing industries.

From the first of these standpoints this exhibition may be said to have been a great success. It certainly was very beautiful and attractive, and in this respect it was typically French, for to the Frenchman such an exhibition would be a failure if it were not beautiful. While there were undoubtedly a few architectural features that might be criticised unfavorably, yet in general the buildings and arrangement of the grounds left little to be desired, although the absence of straight lines in the architectural decorations of the main buildings might not meet with the approval of every American, for in this respect they differed typically from those in the Chicago exhibition. The arrangements and decorations of the characteristically unsightly interiors of long exhibition buildings, were also very tasteful and effective; although the avoidance of a regular system of aisles made a systematic study of the exhibition an almost hopeless task. In some of the attractions, such as the Optical Palace, the underground mines, etc., instruction and entertainment were combined, but as a rule the too numerous "side shows" were for amusement only, and were typically French.

From the other standpoint, that of showing the state of the arts, the exhibition may have been, and undoubtedly was, a success in many departments, but that claim can hardly be made for the electrical industry. For France, Germany, Switzerland and a number of the other continental countries the electrical exhibits doubtless represented the true state of the art and the best general practice as far as these countries were concerned; but the absence of a proper representation from the United States proportionate to the enormous development, made the exhibition an incomplete representation of the present state of this important industry. Any one judging its development in the respective countries by their exhibits, would have obtained a very wrong impression of its progress in the United States, or of the general practice here. We sent over a few excellent electrical exhibits, and they were greatly admired, but there was general disappointment that a country in which the electrical industry is known to be so largely developed, was so inadequately represented. This is all the more unfortunate at the present time when our export trade of manufactured articles is growing so rapidly, and when our electrical practice, in certain directions at least, is thought so well of by foreigners that many of them come over here to study it.

The fact that several of our largest manu-

* Abstract of inaugural address at the 147th meeting of the American Institute of Electrical Engineers, New York, October 24, 1900.

Digitized by Google

facturers have ceded their rights in foreign countries to local companies and therefore claimed to have no interests there, may explain in part the absence of some of the important American electrical exhibits. But unfortunately these local companies do not always follow our practice, and do not manufacture the goods on the same scale and in the same way, so that their exhibits were not as a rule representative of our products.

England also was very inadequately represented in the electrical classes. The English claimed that they were tired of exhibitions, but another reason is no doubt the unfortunate political relation with France. England's exhibits in other groups also seemed to fail to represent the proper magnitude of the respective industries in that country.

Of all of those foreign to France, Germany, its former bitter enemy, had by far the finest exhibits in most of the groups, including the electrical. Another feature of interest politically is that Hungary had in many respects better exhibits than its stepmother country, Austria, and was represented as an independent nation; it bids fair to become one of the greater industrial countries of the East.

The question is frequently asked how the Paris exposition compared with the one in Chicago in 1893. As both were very large and creditable, a comparison becomes difficult and in order to give an opinion of any value one ought to have studied both equally thoroughly and under equally favorable conditions. It is also largely a matter of individual taste, and depends on the nationality of the one giving it, as also on the extent of his knowledge of French. The area of the Paris exhibition was 336 acres, which together with the annex made it about half as large in area as the fair in Chicago, which had about 1,000 acres. The average number of paid admissions seems to have been about double in Paris, due to the fact that it was so managed financially that the average admission was about seven to ten cents as compared with somewhat less than fifty cents at Chicago. Americans seem to have obtained their unfavorable views from antagonistic English papers.

It is thought safe to say that the Paris exhibition, taken as a whole, was more generally beautiful in details, but that it contained no single group as magnificent as the famous Court of Honor, nor were the illumination effects as fine as at Chicago, where they were electrical, while in Paris gas was largely used, the whole of the largest open area, the Champ de Mars, being a brilliant mass of incandescent gas lamps. Neither had as finely illuminated fountains as the exhibition of 1889 in Paris, although the background to the poorly illuminated fountains in the present exhibition, forming the famous Chateau d'Eau or Water Castle, was very beautiful and attractive.

Much else might be said about the exhibition in general, but we as electrical engineers, are more interested in the electrical exhibits. As was already mentioned above, these were representative of the state of the art only as far as the continental countries were concerned, as those from the United States and England were very deficient in scope. It was also stated above that it was less of an electrical exhibition than the one at Chicago. There were moreover no quite novel, epoch-making electrical inventions shown, although a few quite interesting ones that were already known to readers of the electrical journals, were exhibited there for the first time.

One of the striking features was the great prominence of three-phase generators, and their size. One obtains the impression that the three-phase current has triumphed over all the others, including the continuous current, when large amounts of power are concerned, and that it would be poor practice now to install large units of any but the three-phase system unless one is forced to use another.

There was shown a decided tendency toward the use of large units, and quite a number were exhibited having outputs of about 1,000 kilowatts and over. The greater number were for three-phase currents and all formed the fly-wheel of their direct-connected slow-speed engines, while all of the few large continuous current machines exhibited, had to have a separate fly-wheel. That the field is made the revolving part seems to be almost universal practice, as also the distributed winding on the armature. Single and two-phase alternators and large continuous current machines were the exception.

Two very ingenious attempts were shown to compound large, three-phase generators, without commutating the main current, one by Hutin and Leblanc and the other by Boucherot. Both excite their direct current and mechanically coupled exciter by means of the three-phase alternating current, the exciter therefore having a revolving field but fixed brushes: in both, the excitation of the exciter is dependent on the voltage of the alternator and on the main current, in the former by means of a shunt and series field magnet coil, and in the latter by means of a transformer combining the effects of both. To obtain direct current from such an exciter the connections between the commutator and the coils in the former are reversed according to a certain law, while in the latter the armature has several windings differing in their number of turns according to a sine law. Both claim to keep the voltage of the generator constant for different currents and load factors. It will be noticed that there is no commutation except that of the small exciting current in the direct current exciter. Whether they are better or worse than the commutating systems used here practice alone can decide. While they are interesting studies, it does not yet seem to be proved that for large units at least a cheaper attendant than these would require, with his hand on the rheostat and his eyes on the voltmeter, is not a more practical solution.

There were a number of inductor alternators exhibited, which indicates that they are meeting with some favor.

Connecting lamp circuits to three-phase generators does not seem to be considered a sufficiently serious matter to overbalance the advantages of that system. The method used by the General Electric Company of Berlin (that is, the Allgemeine Elektricitäts Gesellschaft, which even in Germany is generally abbreviated to A. E. G.) is simply to distribute the lights as evenly as possible over the three branches. All three mains are run into the buildings of even small consumers, although only two may be used, the third being available for changing over a batch of lamps, if necessary, for balancing. The voltage can thus be regulated only for all three branches together, and not for each separately; but this is not considered a serious disadvantage. The Oerlikon Company, on the other hand, connects lamp circuits between the ends of only two of the three branches of a star-connected winding, the third branch being then idle; this enables the voltage of that single-phase alternating current circuit to be regulated at the machine. By overloading these two circuits 15 per cent. the capacity of the generator is about the same as for motor circuits with a power factor of 0.8. The units in a station can then be alike, and it does not interfere with paralleling, or running motors and lights from the same machine if necessary. Another method used in Switzerland, but only with two-phase generators, is to construct a sort of double machine, the two halves of which may be mechanically displaced relatively to each other to generate two-phase currents for power purposes, or they may be connected in line with each other to generate single-phase currents for lighting.

The high voltage, direct current series system for power transmission and very limited distribution, made another and probably unsuccessful appeal for recognition, in the form of an exhibit by its indefatigable champion, Mr. Thury.

Among the various types of motors, the most interesting was the three-phase induction or Tesla type, which seems now to have demonstrated its superiority over all the others except perhaps the continuous current motor, upon whose field it is however encroaching very decidedly, with the present prospect of becoming its equal in importance. The largest company in Germany and perhaps in the world, estimates that its sale of three-phase induction motors will before long exceed that of its continuous current motors. Its very large factory, including even the rolling mill, is equipped with these induction motors mostly direct connected. There is a single textile factory in Switzerland in which 500 of these motors are used for direct driving. The induction motors almost exclusively of the three-phase and not two-phase type, are being introduced very largely now, especially in Germany and Switzerland.

A nearly uniform type seems to have been adopted by most of the makers. In this, the primary circuit is the stationary one and is distributed over the surface like a drum winding, as distinguished from the coils used in the earlier forms of Tesla. It is this distributed winding which is the chief improvement that has made them such a success; it seems to have been first introduced by Dobrowolsky in Berlin. The larger ones are almost always started with a resistance in the secondary external to the motor; in some cases a short-circuiting device is provided on the rotor for use after starting, so that the brushes may be raised while running to prevent wear. It will be noticed that in some respects this nearly universal practice abroad differs from that in this country, where even very large motors up to 800 hp., if not more, are made without any brushes, being started with a transformed current at lower voltage: others are made with the starting resistances on the rotor itself, which also dispenses with brushes.

One of the applications of three-phase induction motors which is of special interest, and which seems to have a promising future, is to traction. This three-phase traction system, which is scarcely known in this country, is in regular and apparently very successful use on a number of lines in Switzerland. A few of these roads were visited by the writer and as

Digitized by Google

far as could be learned they were running very satisfactorily. The double trolley wire, which is essential, and which has often been urged as being such a serious objection, does not seem to give any trouble at all; each locomotive or car had even two contacts with each wire. Many of the alleged objections are overcome by the use of the contact bar instead of the trolley wheel, which completely avoids any jumping off of the pole, and greatly simplifies the overhead wiring at the switches, which is in fact not complicated at all. The motors are started with resistances in the secondary as usual. There is no complicated controller, as the two motors are always in parallel. The trains start well and without difficulty, and it seems without any very abnormal current. The chief objection to the system seems to be that the running speed is always the same, in which respect it is like a cable road; it is therefore not possible to make up lost time except on a down hill coast, while on steep up grades there is a considerable demand for power as the speed is always the same maximum. No system of efficient speed regulation is used, presumably because none has been found to be satisfactory. This seems to be the real and serious objection to the use of the system in this country, where high speed seems to be an essential requirement. One of the freight locomotives was provided with a purely mechanical device for halving the normal speed, but no other information could be obtained than that it was then in the repair shop.

While three-phase traction in its present state would probably not be practicable here for cities, there seems to be a field for it on long distance interurban lines with few stops, as it is much cheaper. The estimates for the Jungfrau Bahn showed that the first cost would have been 50 per cent. greater if the continuous current had been used on the locomotives, as is done in this country.

Returning to the subject of alternating current generators and motors in general, there is a characteristic difference between European practice and that in this country which seems worth mentioning. Here the coils are usually form-wound and then laid into open slots; there the wires are more generally threaded through completely closed holes as in the Oerlikon and Brown machines, or through holes of which the webs have been cut through with a very thin saw cut, as in the Dobrowolsky machines of the A.E.G. Mr. Brown gives the following reasons for his preference: lower magnetic resistance, smooth surface of core, seamless tube insulation, solid poles, ease in parallel running and avoidance of wedges, binding wire, etc.; his experience is that it takes as long to replace a form-wound coil as to thread in a new one in place. Dr. Behn-Eschenburg, the engineer of the Oerlikon Company, gives his reasons as follows: The smoothness of the surfaces enables the air gap to be made as small as 0.001 of the diameter in induction motors, which is hardly possible with teeth; with a web over the hole of only 0.1 mm. the coefficient of magnetic straying can be reduced to 0.04 and a maximum power factor as high as 0.92 can be obtained; the maximum torque will correspond with 3.5 times normal current, and the possible overload can be 2.5 times the normal; if the holes were changed into teeth, all else remaining the same, the magnetization current would be at least doubled, the straying coefficient reduced to about 0.03, and the best current for the resulting maximum power factor of 0.94 would then be more than doubled and the copper conductors therefore increased; or for the same load the power factor reduced to 0.91; the slotted armature would have to be made longer axially if it is to have the same current at no load as the one with holes; moreover, seamless insulation tubes of micanite can be used in the holes, which if 1 mm. thick will be quite safe for 3,000 volts. However he quite impartially recognizes the favorable features of slots with form-wound coils and admits that they may outweigh the others if a factory is suitably equipped for such work; he believes that under certain circumstances the one, and under others the other, is the better.

Another interesting characteristic difference between American and continental practice, is that here synchronous converters combined with transformers are more generally used for transforming high voltage three-phase currents into low voltage direct currents, while on the continent dynamos driven by high voltage induction or synchronous motors are the rule. Although the favorable features of each are well understood, the reasons given by such a successful constructor as Brown for preferring motor-generators, may nevertheless be of interest here. He states that they can be regulated with ease and precision; no transformers; both parts can be better designed without making concessions; no hunting; ease in starting; no depolarization possible; secondary voltage absolutely independent of the primary. He admits that the synchronous converter is cheaper and more efficient, but claims that the differences are but slight; he has obtained 90 per cent. combined efficiency for a 250 kw. motor-generator set.

In electric railroading there seemed to be comparatively little of special interest to Americans, besides the three-phase motor system and the contact bar, already referred to, both of which deserve more attention here than they are getting.

In electric lighting, one of the most interesting features was the debut of the Nernst lamp. After long and tedious labors on the part of the General Electric Company, of Berlin, the interesting laboratory experiment of Nernst, that a filament of a non-conductor like magnesia becomes a conductor after it is heated—has been developed into a form of high efficiency incandescent lamp, which is now claimed to be ready for the market; but although several hundred were burning there daily it was not possible to buy one. It resembles the usual incandescent lamp except that the bulb is open; the filament is somewhat thicker and much shorter than that of a carbon lamp; the light is very much whiter and more brilliant. It can be lighted with a match, alcohol torch or automatically by a platinum wire preheater with a magnetic interrupter. Either alternating or continuous currents can be used, but the filament must be exposed to the air. The lamps are made for 25, 50 and 100 cp. at 220 volts, and therefore do not yet compete directly with the usual 16 cp. lamp. The efficiency is said to be 1.5 watts per candle, or about twice as good as the present carbon lamp of the same voltage. The filament is said to be made of magnesia mixed with the rare earths like zircon, thorium, etc. The life is claimed to be very satisfactory, though no figures could be obtained, but the perishable parts, valued at only 25 per cent. of the probable cost of the lamp, can easily be replaced, the bulb being open.

The material of which the filament is made has a rapidly falling temperature coefficient, much worse than carbon, which would make it extremely sensitive to changes in voltage. This is overcome by a very ingenious method to which the present success of the lamp is due; it consists in placing a very fine iron wire in series with the filament, the wire being so proportioned that it is heated by the normal current to that temperature (about 450 to 500° C.) at which it has a very rapidly rising temperature coefficient; the resulting characteristic of the two in series is therefore a rising one. This fine wire consumes about 10 per cent. of the voltage. The price of the lamp, it is thought, may be about 50 cents.

The relatively large number of exhibits of switchboard switches for breaking currents of very high voltage, indicates the rapid introduction of high tension currents. In many of them the well-known double horn is used for extinguishing the arc, which is an indication of the effectiveness of this simple device.

A novel departure in switchboards, especially for dangerously high voltage machines, consisted in placing all the switching apparatus belonging to one machine on or under a post or pedestal near the machine itself and so that the attendant faces the machine. The actual switches are under the floor where they are out of the way and easily accessible from a pit below, only the levers, hand wheels and instruments being on the pedestal; the attendant is thereby protected from all possible danger. It is the standard practice of the Oerlikon Co.

The use of silver fuse wire in place of lead alloys, by a very large German company, on the ground of greater reliability and constancy, deserves mention. For the same fusing current the amount of metal volatilized is the least for silver.

Among the cable exhibits there were three for underground work in which multiple cored cables were subjected to 20,000 and 30,000 volts alternating, the insulation in one of these being impregnated paper without any rubber.

A German maker of aluminum goods showed that this metal can be welded without solder or flux by simply heating it to a certain definite temperature at which it softens. The use of aluminum line wires makes this simple method of interest to electrical engineers.

The number of different types of meters exhibited was about equal to the number of their exhibitors, but the Thomson meter in nearly the same form as made in this country, is the one most frequently used; several hundred a day are claimed to be made by the French company which manufactures them. The field for a good, cheap and simple ampere-hour meter for small consumers of continuous current is filled very satisfactorily in France by the O'Keenan meter, of which 11,000 are already installed. In principle it may be said to be like a d'Arsonval galvanometer or Weston instrument, in which however the coil is mounted so that it may revolve continuously, the number of its revolutions being registered. This coil or armature is a shunt to a very low resistance in the main circuit. It is extremely sensitive and the coil requires only 0.6 microwatt to start it; it will register as little as 5 watts in the lamp circuit or 1 per cent. of its range, has a straight line characteristic and is not appreciably affected by temperature changes. A somewhat similar one is about to be introduced in this country and there is no doubt a large field for it.

Digitized by Google

The well-known and ingenious Aron double pendulum meter was well exhibited in various forms, including one for three-phase currents. It is said to be used to some extent in Germany but would probably not find much favor in this country.

An interesting and promising modification in the Thomson type of watt-hour meter, shown in the German section, consisted in using a three coil armature like that in the original Thomson-Houston arc light machines; this enables the same magnetic force to be produced by a much smaller weight of the revolving part, with several attending advantages of importance.

Prepayment meters are meeting with some favor and there might also be a field for them in this country among small consumers.

In telegraphy the exhibit which seemed to attract most attention was the very ingenious printing telegraph system of Professor Henry A. Rowland, of Baltimore. The sender merely presses lettered keys like on a typewriter, and at the other end the message is received in print on a sheet of paper ready for delivery, without requiring any operator. An alternating current of constant frequency is passed over the single line and operates synchronous motors, by means of which the necessary synchronism at the two stations is obtained. The different characters are transmitted by the suppressing of various combinations of the half waves of the current. At the receiver end those waves are received in a large number of relays, various combinations of which operate a few electromagnets for printing the characters and moving the paper laterally and lengthwise. The typewheel revolves continuously and the paper directly beneath it, is struck from below at the exact moment when the desired letter is over the paper. Four messages are sent at the same time in one direction, the line being loaned to each operator in succession for short recurring periods. This is then also duplexed, making eight messages simultaneously over one wire, each, it is claimed, at a speed of 45 words per minute. It does not seem to be used commercially yet, and whether it will be equal to or better than the printing telegraph system which has been in satisfactory commercial use between New York and Chicago for some time, devised by one of our members, can be determined only by equally severe tests.

There were several exhibits of the wireless telegraph system, though none by Marconi's company. The modifications were only in detail and did not include any way of making the system selective. It is now being introduced commercially and there are a number of installations in regular use.

Those interested in the controversy between the vertical and the horizontal telephone switchboard, found a good opportunity to compare them, as each was exhibited by its most ardent defender, the vertical board being advocated by one of our large and prominent companies, and the horizontal by a similarly prominent German company which is introducing it in its country, notably in Berlin. The chief advantage claimed for the latter is that two operators sitting on opposite sides can use the same board and that therefore the length of board for the same number of subscribers is halved.

Electro-chemistry was one of the electrical classes in which the most pronounced recent development was shown, although the exhibits were not sufficiently complete to show the true state of that art. This branch of electrical science has opened what promises to be one of the important fields in which there is an opportunity for great development. Products which not many years ago existed only as rare and expensive specimens, and some which were not even known, are now made electrically by the ton.

Electric furnaces were shown in operation. There was also a very fine exhibition of the extremely interesting collection of products obtained by Moissan in his classical researches. Judging from two other large exhibits, copper is successfully deposited directly in the form of mechanically strong tubes, simultaneously with the process of electrolytic refining. A single company in Germany refines electrically about 5,100 ounces of gold and 24,000 of silver a day.

A very large ozone apparatus was shown in operation, for sterilizing 200,000 cu. met. of water per 24 hours by the Marmier and Abraham process, but a confirmation of the claims made is very desirable.

In accumulators there was shown a general tendency, though not a universal one, to use Planté positives and Faure negatives, a combination which seems to have given the least trouble. Accumulators are now the rule and not the exception in continental lighting and traction stations. Now that the fundamental patents have run out in this country, we ought to use them more freely here. As an electrical flywheel and a comforting reserve in a central station, the accumulator has no equal.

The exhibitions of instruments were very fine, chiefly from France, England and Germany, but it would take too long to enter into a discussion of them here. That a d'Arsonval galvanometer is made with a sensitiveness of 1.2×10^{-10} amperes per mm. deflection, is of interest; it is claimed to be the highest sensitivenes yet reached with that type of instrument. Among the station and laboratory instruments which are not generally used in this country, put which are very convenient, are the phase meters of Dobrowolsky, indicating directly the difference in phase. A curious, but characteristically Europen criticism of a certain world-renowned type of American instrument, was, that "they are bad because they are expensive."

DYNAMO ILLS AND REMEDIES.*

A dynamo or motor, carefully installed and properly running, is truly a thing of beauty to those who have the care of it, and a source of satisfaction to its owner. Trouble, however, in one form or another is sure to come sooner or later, depending on the grade of the machine and the skill and care in handling.

It is therefore likely that a few hints as to the cause and remedy of such troubles will be acceptable to those who have the care of this class of machinery.

Obviously, the promptness with which such troubles are located and removed will have much to do with the success of the plant. Often, indeed, considerable expense is incurred in removing a fault, which with a little intelligence could have been remedied at trifling cost.

For instance, so slight a thing as a loose connection will often cause the shutting down of a whole factory with scores of hands. Other troubles equally as simple but not so easily located will cause annoyance and delay. In such cases, some knowledge on the part of the man in charge in locating troubles would have enabled him to overcome the difficulty and save delays and consequent loss.

Fortunate it is that the machines in question are mechanically so simple in their construction. With the exception of commutator and brushes there are but two wearing parts, the two bearings which support the shaft of the armature, quite in contrast in its simplicity to the steam engine with its multiplicity of wearing parts, oil cups and valves.

From the fact that the dynamo or motor has so few parts, we are able to classify their troubles through their effects under five heads, which are:

1. Sparking at commutator.
2. Heating of the various parts.
3. Noise and speed.
4. Motor stops or fails to start.
5. Dynamo fails to generate.

Any and all of these effects are quite obvious, even to a casual observer; still a most careful and thorough examination should be made of the entire machine in order to be sure of facts and to avoid jumping at conclusions.

In the consideration of troubles as classified above the following order will be observed: First, the cause; second, the sympton in detail; third, the remedy and how effected.

As is very often the case, a symptom may be developed in a machine from several causes, or a cause may result in several symptoms. We shall, however, endeavor to make the distinction as clear as is possible without the help of the actual machine for illustration.

Sparking at the commutator is caused, first, by the armature carrying too much current, due usually to an overload; in the case of the dynamo, too many lamps in circuit; or in the case with the motor, excessive frictional load, from hot bearings, armature striking the pole pieces, belt too tight, or in general, too much mechanical work to be done. Excessive voltage on constant potential circuits will also overload the system.

The symptoms are a continuous sparking at the commutator during the time of maximum load and tendency to slipping of the belt.

After a continuous run, the armature becomes very much overheated and will burn out if the load is not lightened.

In this, however, there is an exception, constant current arc motors. As the heating effect depends on the square of the current multiplied by the resistance ($C^2 R$), both of which factors are constant in this instance, it is quite possible to overload machines of this type till the armature stops without risk of burning it out.

Excessive friction load is readily detected by turning the armature around by hand.

Hot bearings will be treated more in detail under the head of heating of the various parts.

An excess of current is, of course, at once evident at the ammeter, and this may be taken as a conclusive test for all such overloads.

The remedy, for troubles of this nature, is obviously to reduce the load and eliminate partial short circuits in the line and leads as far as possible.

Constant potential motors, especially those above five horse-power, are frequently subjected to overloads and strain at starting.

Digitized by Google

If the starting-box has too little resistance or is turned on too rapidly, it will cause the armatuer to start with a jerk and spark badly at first. A properly designed starting box will remedy the evil in the first instance, and in the latter case, the exercise of proper care in starting. The handle of the starter should be allowed to remain an instant on the first and second contact points till the armature has attained some speed.

Again, brushes are sometimes not set at neutral points. The symptom of this trouble will be a sparking and cutting at the commutator, the intensity of which will vary with the shifting of the brushes.

The remedy can best be explained by referring to Fig. 1, which shows the proper position of the brushes. The points where the brushes are resting on the commutator where the greatest E.M.F. and the least sparking are obtained, are called the neutral points, as represented in the cut by the points "A" and "B."

The line joining these two points has been termed the diameter of commutation. It will be noted that this line is not at right angles to the line joining the centers of the pole pieces, but is shifted through a small angle, depending on the direction of rotation and whether the machine is acting as a dynamo or motor.

With the dynamo, the brushes will be given

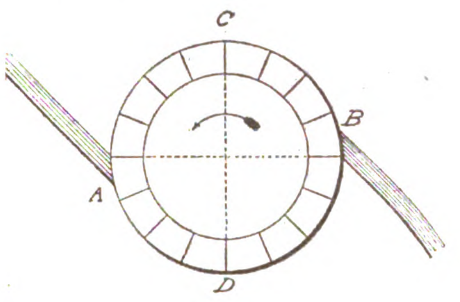

Fig. 1.
The Diameter of Commutation.

a forward lead, that is, they will be shifted from the horizontal in the direction of rotation.

With the motor, the shifting of the brushes will be against the direction of rotation and will be given what is termed a backward lead.

In most dynamos and motors the exact position of the neutral points cannot be fixed, but will vary according to the load of the machine. For instance, in the case of a dynamo with a given number of lights burning, the brushes may be properly set at the neutral points and run without sparking. Now let the number of lights burning be increased or diminished to any considerable extent and sparking, more or less destructive, will commence and continue till the brushes have been shifted to the new neutral points by means of the rocker arm. These points are determined only by trial.

This shifting of brushes, or giving them a lead as it is called, is necessitated by armature reaction or the magnetizing effect of the current in the armature, tending to create a powerful magnetism which distorts the field.

Right here we will state that there are some dynamos and many motors in which it is not necessary to shift the brushes, no matter how much the load changes. In these the field has been made strong enough to overpower the armature reaction. Again in another class of dynamo, the moving of the points of contact is taken advantage of as a method of increasing or decreasing the E.M.F. This is the case of constant current arc machines.

It is not only necessary to shift the brushes to the neutral points by means of the rocker arm, but care should be taken to see that the brushes are diagonally opposite each other. This can be accomplished by counting the number of segments of the commutator, measuring with a piece of thread or other device, marking the opposite segments, and setting the brushes to this mark.

The setting of brushes is perhaps the most important duty of the dynamo tender, for a

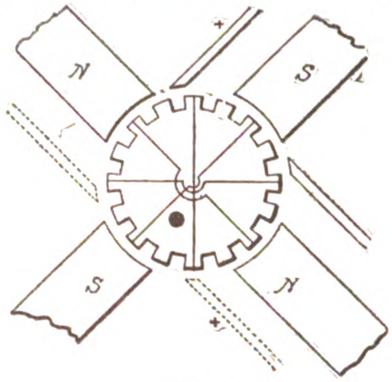

Fig. 2.
Circuits of Cross Connected Armature. Four Poles; Two Brushes.

brush, a fraction of a segment out of position, will often cause serious sparking.

Exceptions to the rule for setting brushes diametrically opposite will appear in the case of multipolar motors with cross connected armatures.

These machines may be supplied with two sets of brushes or as many sets as there are poles. For instance, four pole machines with two sets of brushes require them to be set at 90 degrees apart; 6 pole at 60 degrees, or 180 degrees, and so on.

Fig. 2 shows the armature connection and the position of the brushes in a four pole machine with cross connected armature. The arrows mark the direction of the current in the armature connection. It is apparent, therefore, that no one should attempt to set the

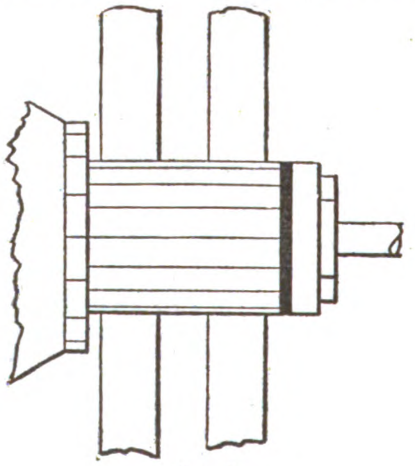

Fig. 3.
Commutator in Good Condition.

brushes on such a machine without first determining from a blue print or other source their correct position, and then keeping them there.

Should the brushes be set very far out, they will probably cause the safety fuse to blow and in the case of a dynamo it will fail to generate.

The commutator may have high bars or low bars due to loose shell or an unusually hard specimen of copper.

A poor connection between the leads and the tongue of the commutator segment, will also develop a flat, hard mica between the segments which does not wear down as fast as the copper; all of these produce a rough commutator.

The symptom in this case will be a chattering of the brushes, accompanied by sparking, which is sometimes apparent by the sound. By touching the commutator with the top of the finger the least roughness is at once apparent. Turn the armature slowly by hand when any eccentricity will be indicated by a rise and fall of the brushes.

The commutator as it should be is represented in Fig. 3, with brushes properly set and the surface of the commutator smooth and glossy.

Accompanying is a sketch of the same commutator in bad condition. The commutator being scarred and rigid and the brushes badly set.

In cases where the commutator exhibits eccentricity or is deeply cut, the armature should be taken out, accurately centered in a lathe and the commutator turned off, taking off as light a chip as possible.

In large armatures it is often more convenient to rig up a special slide rest and turn off the commutator while the armature is turned at slow speed in its own bearings.

A loose bearing will also cause chattering of

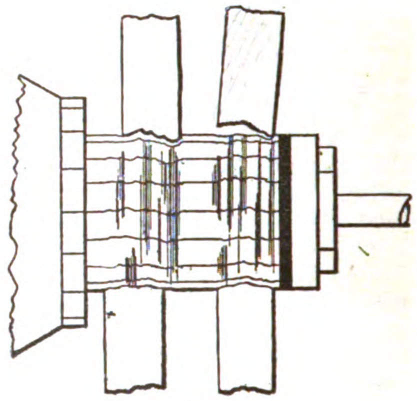

Fig. 4.
Commutator in Bad Condition.

the brushes with the attendant sparking and cutting of the commutator. If the bearings are loose and worn they should be re-babbitted or new ones put in.

A slide rest which clamps on to the pillow block in place of the rocker arm is shown in Fig. 6.

A slightly rough commutator can be dressed down with a fine file and given a final application of fine sand paper, the armature being turned at medium speed.

If the machine in question is a dynamo it is advisable to raise the brushes, start the engine at medium speed and apply the file or sand paper, or both, as the case may be, thus avoiding clogging the brushes with dirt and copper dust.

With a motor it is different, as we must rely on the current to turn the armature. It is therefore an exceedingly dangerous practice to use a file, although sand paper may be applied without danger. It is a good plan to put a little oil on the sand paper, for in this way the particles of copper are gathered and prevented from flying into the armature, thus increasing the danger of short circuits or burnouts.

It may be stated as an axiom that copper dust and metal filings in general should not be allowed to collect about a dynamo or motor.

Digitized by Google

For this reason emery cloth should never be used on the commutator, as the particles of emery are so sharp they become lodged in the copper of the segments, thus converting the commutator into a veritable grinding tool. Again the particles get into the mica and cause short circuits.

Brush-holder screws sometimes become loose and the brushes get tipped up so they touch only at one point. Very often vaseline or oil has been applied too freely and the commutator has become dirty. The springs which give tension to the brushes may have lost their temper from carrying the current, though this is an indication of a faulty design of brush-holder. The bearing part may have been clogged for some reason so that the holder does not work freely—though the spring may

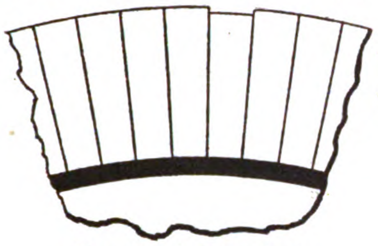

Fig. 5.—A Low Bar.

still be good. Hard carbons that will not adjust themselves in wearing to the commutator, and which sometimes offer exceedingly high resistance, also induces sparking at the commutator.

Copper brushes can best be filed for adjustment to the commutator in a jig made for the purpose.

The simplest way to adjust carbon brushes is to first wrap a piece of sand paper around the commutator, having the rough side of the paper turned out; then set the carbon brushes down tightly against this surface, revolving

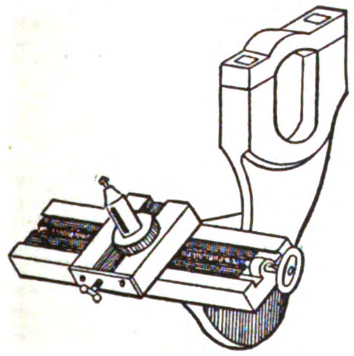

Fig. 6.
A Tool Clamping on Pillow-Block Used to Turn Off Commutators.

the armature by hand while the brushes will be rapidly and accurately shaped to the surface.

The best way to keep a commutator clean is to wipe it at intervals with a piece of cotton cloth or felt slightly moistened in vaseline.

A motor with short circuited coils or bad grounds will draw excessive current, even though running free of load. A dynamo will require considerable power though there is no evidence of power in external circuit; in either case violent sparking will result.

The symptom most apparent will be a heating of the coil or coils affected, and the attendant will become warned of the danger by the odor of the burnt cotton insulation.

A short circuited armature coil often results from allowing copper dust to collect back of the commutator or when excessive sparking of the brushes has formed little bridges of metal across adjacent commutator segments.

Short circuits in parts of the coils of an armature frequently occur from injuries to the insulation, from external mechanical sources, for instance, the dropping of little particles of material in the spaces between the armature and pole pieces while the armature is in motion. A screw, for instance, or even little balls of waste, and more frequently oil and dirt, cake on the faces of the pole pieces, scraping the insulation off the wire.

A piece of iron, a screwdriver or key, for instance, held between the field magnet, near the revolving armature, will vibrate very perceptibly as a short circuit coil passes.

In the case of a motor, an armature affected with a short circuited coil will revolve slower than usual and unsteadily, while in aggravated cases it will draw up with a jerk before the pole piece.

Ills such as those described as short circuits due to deposits of copper dust back of the commutator or the bridging over of segments from sparking may be located by careful inspection and removed by scraping clean the mica insulation between the segments.

Short circuits, due to mechanical injury to the insulation of the wire of the armature, require careful handling, as these injuries generally extend before the first layer of wire.

In most cases it is possible to carefully lift the wires, one at a time, high enough to wrap it with silk tape.

Wires thus raised and insulated must be carefully pounded back into place with a wood block or mallet, the affected part being then treated with a coating of good shellac.

A short circuit which is in the coil itself and below the surface cannot be treated thus and the only real remedy is to rewind the coil.

Two or more grounds in an armature, occurring usually from insufficient insulation on the core, are equivalent to a short circuit and must be treated in the same way, viz., by re-insulating and rewinding the armature.

The commutator will flash violently when the broken coil passes under the brush and it will be found that the mica, surrounding the segments attached to the broken coil, will be blackened and burnt and gradually pecked away.

This break will often be found in the leads where the armature wires connect with the commutator, as in some types of machines they are subject to heavy drag. Usually they can be easily repaired by splicing.

An overload may cause the soldered connection of the leads to the commutator to melt and thus develop a break. The only available remedy is to solder in the leads again and guard against overload in the future.

Care must be exercised in the soldering process lest drops of molten solder drop in behind the commutator and short circuit some of the segments.

When the trouble cannot be so easily located and is evidently in the interior of the coil, the coil thus affected will have to be rewound.

The trouble, however, may be temporarily remedied by cutting out the coil, either by bridging over the disconnected segment with a drop of solder or by staggering the brushes, as it is called, that is, setting one of a pair a little ahead and the other a little back of their normal position, which is equivalent to bridging over the break.

In adopting this method, care must be taken not to short circuit a sound coil, as this will cause sparking and a dangerous heating of the affected coil.

These devices are at best only "make shifts" and should only be adopted to prevent a very undesirable stoppage.

Field troubles cause sparking at the brushes and are of two kinds, open circuits and short circuits.

A dynamo thus afflicted does not generate at all or does not come up to its full electromotive force. The pole pieces are not strongly magnetic.

A constant potential motor has a tendency to race unless the field is very weak or is lacking altogether, in which case it may either run slow or stop and blow the fuse.

The cause for such trouble is usually a broken circuit or a partial short circuit in one or both of the fields.

In order to test for an open circuit in the field of a motor, block the brushes up from the commutator with pieces of wood or paper, then turn on the current, remove the field wire from its binding post and absence of spark at the breaking of the circuit will indicate a complete break somewhere in the circuit.

In cases of field trouble in isolated dynamos where current is not obtainable, it will be necessary to remove the terminals of the field circuit from their binding post and ring through it with a magneto or bell and battery.

Short circuits in field coils may be determined by measuring, with the proper instruments, usually a portable bridge and galvanometer, the resistance in each magnet coil. Any appreciable difference in the resistance of the magnets will indicate that the one of least resistance has been short circuited.

A machine thus affected will spark more at one brush than at the other when running, and it will further be noticed that the short circuited magnet will heat less than the sound one, which in turn will be above the normal.

The remedy for such troubles is to remove the faulty magnet and unwind the wire on it till the break or ground is found, when the fault may be repaired and the wire wound back again.

It may be stated here that a frequent cause of short circuits in field magnets and armature is due to the soaking they receive from oil thrown out by faulty bearings.

Oil, soaking into a field, seems to have the effect of rotting the insulation on the wire and a short circuit or ground is the result.

A carbon brush of high resistance may cause sparking because of its poor contact with the commutator. A charring or burning of the brush about the edges will be noticed and the brush itself becomes hot, in which case supply a softer brush.

Again, vibration in the machine due to insufficient foundation is frequently a cause of sparking. It will be found to decrease when the machine is braced. Often nothing more is needed than a slight increase in the tension of the brushes. The better way, however, is to secure the machine firmly to a good substantial foundation of masonry.

A chattering of the brushes is sometimes due to a dirty and sticky condition of the commutator. This is apt to be the case with radial carbon brushes. To remedy this wipe the commutator clean and then lubricate it with oil or vaseline rubbed on with a piece of cotton cloth or felt.

A trouble to which the same armatures are

Digitized by Google

liable, and which is sometimes very difficult to locate, is what is termed a flying break.

This will develop after the armature is in motion, causing violent sparking with every indication of an open circuit, but will not be apparent to tests made when the armature is stationary. It can usually be found by careful inspection of the back and can be repaired with thoroughly good soldered joints.

Lundell Octagon Type Motors for Automobiles.

Experience has demonstrated the fact that electric motors are the most satisfactory method of operating self-propelled vehicles. The electric carriage is the most convenient, the simplest, the safest and most desirable from all standpoints. It runs smoothly and quietly and is easily controlled.

The Sprague Electric Company, whose reputation for building electric motors has never been surpassed, has designed new motors for automobiles that will meet the demands of the most critical manufacturer. These motors were designed under the personal supervision of Mr. Robert Lundell, the well-known inventor of electric motors, and are guaranteed to stand the requirements of the most exacting conditions.

The same care that has made the reputation of the Lundell motors has been used in the selection of material and the construction of each detail, which, combined with the correct principle of design, has produced a motor that is compact, reliable and unequalled for efficiency.

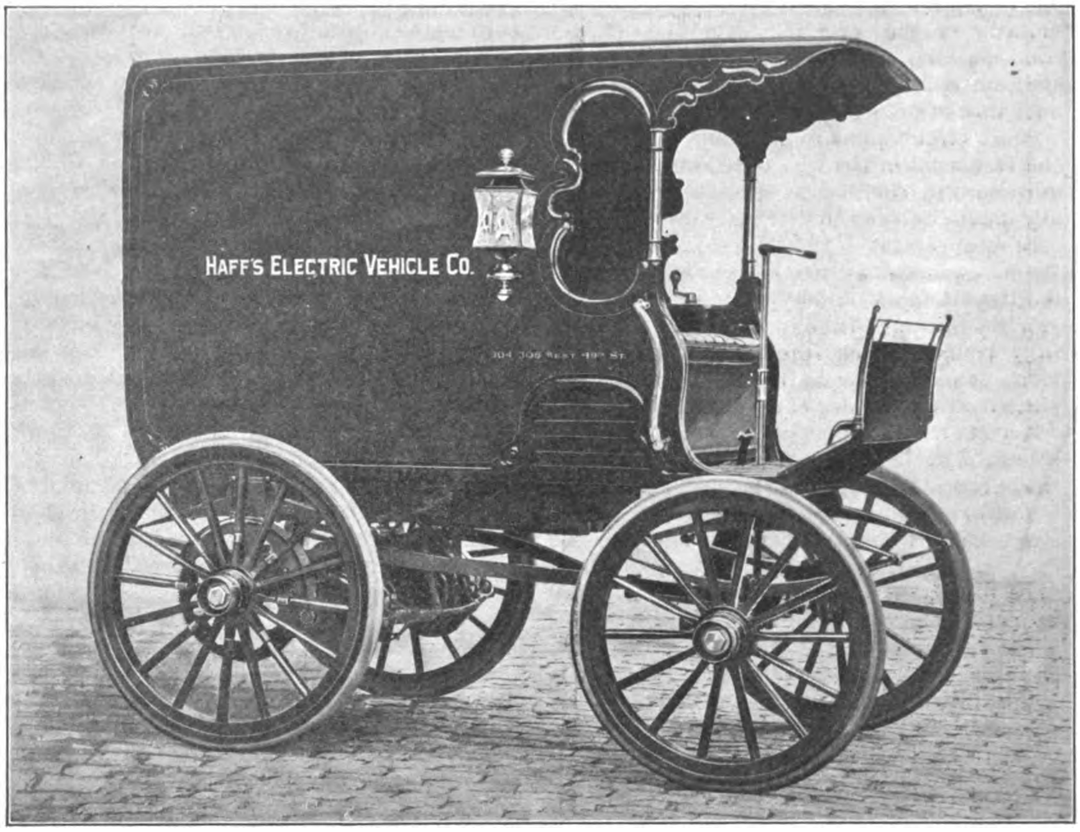
The Lundell octagon type motors are designed especially for automobile service, and are perfectly rigid and free from rattling or shaking of parts due to vibration. They are made for either single or double motor equipment as may be desired. In the single equipment the motor having a double commutator is used, while the double equipment takes two motors each with a single commutator, the idea being to use two commutators to each vehicle.

The motors are usually wound for 80 volts, but can also be wound for other required voltages.

When the octagon type of motor is used in connection with different apparatus (other than automobiles) it is ordinarily furnished with feet. The feet, however, are dispensed with for automobile work and the end castings are furnished instead, with lugs or bearings to suit the style of suspension and running gear.

These motors are entirely enclosed, but have removable covers over the commutator. They are practically dust and water proof and invulnerable to accidents or injuries.

A controller especially designed by the Sprague Electric Company enables the operator to have perfect control of the vehicle at any time, and will withstand the hard usage resulting from frequent starting, stopping and heavy overloads. The matter of overloads has been carefully considered, enabling the motors to respond to a demand far in excess of their rated capacity without injurious heating or sparking.



Electric Vehicle Equipped with Lundell Motors.

PERSONAL MENTION.

Mr. Duncan McDonald, superintendent of the Montreal (Can.) Street Railway, has been appointed to the general superintendency of the General Traction Company of Paris, France, and will enter upon his duties about the first of the year.

Mr. James Shaler Hodges, A. B., has been appointed an assistant instructor in the Rensselaer Polytechnic Institute at Troy, N. Y.

INCORPORATIONS.

The Pearne Electric & Manufacturing Company, Grand Island, Neb. Capital stock, $150,000. Incorporators: F. D. Pearne, W. S. Pearne, W. D. Pearne, L. W. Lyons and T. O. C. Harrison, all of Grand Island.

The Central Electric Company, Louisville, Ky. Capital stock, $10,000. Incorporators: J. S. Carill, P. M. Gelatt and W. C. Hines.

The Columbia Electric Light Supply Company, Jersey City, N. J. Capital stock, $50,000. Incorporators: C. E. Sutherland, Yonkers; Frank L. Eckerson, New York, and George W Flaacke, Jersey City.

The National Safety Third Rail Company, Charleston, W. Va. Capital stock, $5,000,000.

The Union Electric Company, Camden, N. J.—to furnish electricity. Capital stock, $200,000. Incorporators: F. R. Hansell, G. H. B. Martin and William F. Eidell.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 20, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

661,975. Trolley. Henry S. Goughnour, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Filed Dec. 12, 1899.

662,009. Trolley. Frank A. Merrick, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Filed Jan. 18, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

661,986. Supporting Block or Bracket for Electric fixtures. John W. Heiser, Chicago, Ill. Filed Dec. 30, 1899.

662,048. Electric-Arc Lamp. James J. Wood, Fort Wayne, Ind., assignor to the General Electric Company of New York. Filed July 28, 1898.

662,369. Terminal Connection for Electric Lamps. Alexander J. Wurts, Pittsburg, Pa., assignor to George Westinghouse, same place. Filed Jan. 27, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

661,972. Controller for Electric Motors. Frank W. Garrett, Johnstown, Pa assignor to the Lorain Steel Company of Pennsylvania Original application filed March 26, 1900. Divided and this application filed June 5, 1900.

662,038. Controller. Emmett W Stull, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Filed Dec. 28, 1899.

662,042. Dynamo-Electric Machine. Francis W. Throop Niagara Falls, N. Y. Filed Jan. 29, 1900. Renewed Oct. 15, 1900.

662,049. Automatic Circuit-Breaking Apparatus. Granville T. Woods Monsey, N. Y. Filed Aug. 24, 1898.

662,316. Magneto-Electric Machine. Frederick R. Simms, London, Eng., and Robert Bosch, Stuttgart, Germany. Filed July 5, 1900.

662,358. Controller for Motors and Brakes of Electric Cars. Adolphe Grossman, New Orleans, La. Filed July 5, 1900.

662,375. Multiple-Voltage Controller. Gano S. Dunn, East Orange, N. J., assignor to the Crocker-Wheeler Company of New Jersey. Filed March 21, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

661,988. Telephone Receiver. Harry H. Hipwell, Allegheny, Pa., assignor to Hipwell Manufacturing Company, same place. Filed Feb 10, 1900.

MISCELLANEOUS.

661,971. Control of Electric Motors. Frank W. Garrett, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Filed March 26, 1900.

662,020. Means for Rapidly Transmitting Telegrams. Anton Pollak and Josef Virag, Buda-Pesth, Austria-Hungary, assignors of one-half to Vereinigte Elektricitats Actien-Gesellschaft, same place, and Friedrich Silberstein, Vienna, Austria-Hungary. Filed May 9, 1899.

662,021. Method of Rapidly Transmitting Telegrams. Anton Pollak and Josef Virag, Buda-Pesth, Austria-Hungary, assignors of one-half to Vereinigte Elektricitats Actien-Gesellschaft, same place, and Friedrich Silberstein, Vienna, Austria-Hungary. Filed Dec. 21, 1899.

662,032. Automatic Fire-Alarm Device. Ernest F. Sitts, Herkimer, N. Y. Filed July 10, 1899.

662,039. Control of Electric Motors. Emmett W. Stull, Johnstown, Pa., assignor to the Lorain Steel Company of Pennsylvania. Application filed June 8, 1900.

662,090. Process of Manufacturing Carbons for Electrical Purposes. Eduard Pohl, Kalk, Germany, assignor, by direct and mesne assignments, to Adolph Schenck, Bergedorf, Germany. Filed Aug. 29, 1899.

662,234. Circuit-Closing Device. Edgar W. Hazazer, New York City. Filed Oct. 7, 1899.

662,277. Separator for Secondary-Battery Plates. Henry Leitner, London, Eng., assignor to the Electrical Undertakings, Limited, same place. Filed May 28, 1900.

662,278. Aural Battery. Christopher W. Levalley, Milwaukee, Wis. Filed July 17, 1900.

662,286. Electrolytic Apparatus. Emanuel Motz, Jefferson, S. C. Filed May 26, 1900.

662,315. Sparking Igniter for Explosive-Engines. Alfred J. Signor, Elkhart, Ind. Filed Feb. 1, 1899.

DESIGNS.

33,593. Case for Slot-Telephones. William A. Foss, Cleveland, O., assignor to the American Bell Telephone Company, same place. Filed June 22, 1900. Term of patent, 7 years.

33,594. Telephone-Pole Box. William D. Gharky, Philadelphia, Pa. Filed Sept. 7, 1900. Term of patent 14 years.

THE TELEPHONE WORLD.

Another Independent Company for Minnesota.

It is rumored that a plan is on foot to organize a local independent telephone company to be owned and controlled entirely by citizens of Minneapolis and St. Paul. The projectors believe that with local busines smen interested, with ample means, there would be little difficulty in procuring the necessary franchises. If the present plan is carried out, every telephone user will, so far as possible, be interested as a stockholder, so that the earnings of the system will inure to the benefit of the patrons. The failure of the Mississippi Valley Telephone Company to extend its system is believed to have influenced the men behind this project.

It was recently reported at Atlanta, Ga., that the Southern Bell Telephone & Telegraph Company and the Cumberland Telephone Company, operated exclusively in the Southern States are to be consolidated under a single management in the immediate future. Following this will occur the consolidation of all the Bell systems, including the consolidated companies of the Cumberland and Southern Bell, the Chesapeake and Potomac, the Chicago, New York and Boston, and all other systems under the direct management of the American Bell Telephone & Telegraph Company, with headquarters in New York.

The Black River Telephone Company is to construct a toll line south of Boonville, connecting Forest Port, Alder Creek, Remsen, Prospect, Trenton, Holland Patent and Utica, N. Y. The company now has connections north of Lowville with Carthage, Watertown, Antwerp, Gouverneur and all principal points to Ogdensburg; also south and west to Oneida, Syracuse, Clinton, Oriskany Falls, Waterville, Newport, Herkimer, Ilion, Frankfort, in the State, and all intermediate towns and villages. The company has direct telephone connections with about 125 toll stations. It is operating six exchanges and has seven more to build.

The Missouri & Kansas Telephone Company is considering making a proposition to the council of Kansas City, Kan., for another franchise. One of the concessions that will be asked for is the privilege of putting its wires underground, as the company desires to abandon its overhead wire system. This contemplated action on the part of the company has caused the council to temporarily postpone any action looking toward the reduction of telephone rates, and the ordinances that have been prepared will not be introduced if the proposition for a new franchise is presented in the near future.

The claims and judgments against the Mississippi Valley Telephone Company of Minneapolis, Minn., amounting to over $17,000, were satisfied a short time ago, and the company has been released from the writs of attachments which have been hanging over its head. All claims were wiped out, and the work of extensions and improvements will be pushed with all vigor possible by J. C. Hubinger and his assistants.

J. C. Kelsey, who has charge of the switchboard in the Minneapolis, Minn., office of the Northwestern Telephone Exchange Company, and five employes of the company, recently tried an experiment with a wireless telephone which, it is said, proved a success. The conversation was carried on from a distance of 200 yards, and a good, clear sound resulted.

A large telephone cable has been laid across the Ohio River above Rising Sun, Ind., by the Green Brothers, connecting their telephone system in Boone County, Ky., with their exchange centers in Ohio, Dearborn, Switzerland and Jefferson Counties, and about fifty Indiana cities. One was recently laid at Carrollton, Ky.

The Boyle Citizens' Telephone Company, which was organized in Perryville, Ky., about one year ago, and which has wires throughout Boyle, Washington and Mercer counties, has sold out to the East Tennessee Telephone Company, which will take possession at once.

The work of remodeling the telephone wire system in Santa Barbara, Cal., is about to be started. The company has greatly increased its business in that city during the last year. Its wiring system is therefore sadly inadequate to what is required of it.

Independent lines have bought the Mt. Sterling, Ky., plant, and will operate it in conjunction with the rest of the system in that State. A $75,000 plant is being put in at Louisville.

The Erie Telegraph & Telephone Company will abolish its Lowell, Mass., offices about December 1 and transfer the entire clerical force to Boston and New York.

Milwaukee 'Phone Invention.

Patents have been applied for and are about to be issued says a Milwaukee, Wis., paper, for an electrical device, called the Multiplex Telesig, a simple telephone system, calculated, upon long party lines, to allow any subscriber to be called without in the least disturbing others upon the same line. The inventors are W. S. Burnett and W. H. Goodhal of that city.

The call on the line is indicated at the main office by a telegraph key which is manipulated by the operator so as to tick off any of the dots or dashes of the Morse telegraph code. The principal technical device of subscriber's instrument is a cylinder. Compactly set around this cylinder and parallel with its shaft are small pins, which are depressed or remain in position as the operator dictates upon the key at the other end of the line. When the end of the particular call has been reached at the main office in the course of the dictation, a key in the box answering to its number falls into the cylinder and the bell rings up the 'phone of that especial number. Every key is, of course, different and answers to the subscriber's list registered at the main office. The pins in the cylinder always fall back into place at once by a self-acting spring and are thus at all times ready for a new impression.

The machine will be introduced to the public within seven months or so. It is possible with this system to maintain on a single circuit of telephone service, station signaling on railroads, police and fire signaling, messenger service, etc. In laying submarine mines for the protection of coast lines or cities any number of torpedoes could be placed upon a circuit and any one exploded without in the least disturbing any of the others. In wiring hotels, instead of running a net work of wires to the desk, one wire will be run down and any guest called up without disturbing the others.

In the police department at present the policemen can get the chief, but the chief is unable to get the policemen individually. At present one of the inconveniences of party lines is that one subscriber hears a bell rung for another subscriber and can listen if so minded. The new invention insures privacy.

It is predicted that the Bell Telephone Company and the Citizens' Company are going to have trouble in Medina, N. Y. The Citizens' Company had a franchise which expired and since its expiration it has started to put in the plant. The Bell Company there gives poor service. The Citizens' Company has secured about 90 subscribers in Medina, and the board of aldermen is somewhat perplexed over what action to take, as part of the citizens favor one company and part the other. The Citizens' Company will be connected with Middleport, Gasport, Lockport, Tonawanda, Niagara Falls and Buffalo, and with the Home Company of Rochester, and it claims that any action the trustees may take in the matter will not affect it because it has a decision in a case tried in Cortland, N. Y., which states that if the new company has subscribers in the village it may erect poles and establish its business, even though it has no franchise from that village, and can obtain none.

The Enterprise Telephone Company is putting in new poles, and making other improvements at New Martinsville, W. Va. This company has six lines leading from New Martinsville and reaches Clarksburgh, Weston, West Union, and most of the towns in the center of the State. It will put in a line to Wheeling by way of the Ohio River towns.

According to a report from Kansas City, Kan., an effort will be made to secure the passage of a bill at the next session of the Legislature giving cities of the first class the right to tax telegraph and telephone companies for each pole they erect on the streets. The Wyandotte County delegation will be asked to vote for and support the bill, and those who are interested in municipal reform expect to do all they can to have such a bill enacted into law.

The Minnesota Central Telephone Company will put in a local exchange at Buffalo, Minn. The central office will be connected with the company's main line and that of the Northwestern as well.

It is said that on January 15, 1901, the American Telegraph & Telephone Company will issue 80,000 shares of new stock to its shareholders at par ($100), thereby completing the issue authorized in the early part of this year.

The common council of Little Falls, N. Y., has granted a franchise to the Central New York Telephone & Telegraph Company.

A telephone exchange will be established at Coronado, Cal.

A new telephone company has been granted a franchise by the Paris, Tex., city council. Home capital is interested in it

A dispatch from St. Petersburg states that the telephone franchises were sold at auction on November 20. The new regime begins in November, 1901. The Government has prescribed the conditions of rental, and the franchises were given to the parties fixing the lowest subscription. The St. Petersburg municipality won in that city, agreeing to demand 45 rubles annually, compared with 250 rubles hitherto charged. The rates for subscriptions accepted are: Odessa, 48 rubles; Riga, 57 rubles; Warsaw, 69 rubles, and Moscow, 79 rubles. The prices for restaurants, hotels, etc., are 30 per cent. higher for a single user, and 10 to 20 per cent, lower for telephones in general use, the custom being to place telephones in a corridor for the use of the entire building. The long-distance lines remain the property of the Government.

A new telephone company to be known as the Fox River Valley Telephone Company, and to operate between Neenah, Menasha, Appleton, Little Chute and Kaukauna, has been organized in Appleton, Wis. The organization will begin with a capital stock of $25,000 which will be increased soon. The company will act in conjunction with the Wolf River Company, that has franchises in most of the above cities and by permission of which Appleton will be entered. All wires are to be underground and work will be begun in the spring. The following officers were elected: President, J. S. Van Nortwick; vice-president, John McNaughton; secretary, A. L. Hutchinson; treasurer, John Baer.

H. D. Stroud, of Minnesota, but now in the employ of the Chicago Telephone Company, has invented a meter for telephones. The meter is placed beside the subscriber's telephone and indicates to him the number of calls made. The present system of measured telephone service is unsatisfactory. Under the meter system he can tell at a glance just how many calls he has made.

The Cortland, N. Y., Home Telephone Company has made a contract and secured a right of way by which it will build a telephone line from Cortland to Syracuse, connecting with the plant of the Syracuse Telephone Company in that city. The contract for setting the poles between Cortland and Syracuse will be let at once and the line is intended to be in operation by January 1, 1901.

A telephone war will be inaugurated in Columbus, O., about January 1 between the Central Union, or Bell Company, and the Citizens' Telephone Company, or independent concern. The Bell people will make the cut. Residence telephones will be from $20 to $24 a year on single and from $12 to $17 for party lines. The general officers of the Central Union Company are in session there and confirm the story of the reductions.

John T. Colling, R. E. Daly, Edwin Heil, Thos. Kelly and John M. Scott of Cincinnati, O., have incoporated the Cincinnati District Telegraph Company, with a capital of $1,000. They will do a general telegraph and telephone business in Ohio and other States.

The Ottumwa, Ia., Telephone Company has filed articles of incorporation amended so as to increase the capital stock from $40,000 to $75,000.

The city council of Arcadia, Fla., recently gave J. J. Head and his associates a franchise to put in a telephone system.

TELEPHONE INCORPORATIONS.

The South Whiteley Telephone Company, South Whiteley, Ind.—to operate a telephone exchange. Capital stock, $3,000. Incorporators: A. H. King, H. E. Rauman, F. S. Remington, D. C. Scott, all of South Whitley.

The Philadelphia Messenger 'Phone Call Company, Wilmington, Del.—to use electricity in all its branches. Capital stock, $100,000.

The Vermilion County Telephone Company, Danville, Ill. Capital stock, $60,000. Incorporators: Charles F. Haworth, William Henderson and John Fletcher.

The Gaston Telephone Company, Stanley's Creek, N. C. Capital stock, $10,000. Incorporators: M. C. Hunter, E. L. Pegram, Jr., and C. D. Homesley.

The New Washington Telephone Company, New Washington, O. Capital stock, $5,000.

The Yorktown Telephone Company, Yorktown, N. Y.—to operate lines in Westchester County. Capital stock, $2,500. Directors: T. F. Tompkins and E. B. Kear, Yorktown Heights; C. W. Pugsley, Peekskill.

GENERAL ELECTRICAL NEWS.

Lighting.

Allegheny, Pa.—The Pennsylvania Light, Heat & Power Company will erect an electric light plant.

Almonte, Ont.—The citizens of this city have voted to issue $30,000 in bonds for erecting an electric light plant.

Arlington, Ore.—Messrs. Jackson & Nichols, of Everett, Wash., propose to put in an electric light and waterworks plant here as soon as arrangements can be made.

Auburn, Neb.—A company is being organized here for the purpose of asking the city council for a franchise to put in an electric light plant.

Baltimore, Md.—The Roland Park Company will issue $200,000 of bonds for improvements and extensions to the present electric light plant.

Chain of Rocks, Mo.—The measure providing for the erection of an electric light plant here, and also to furnish power to illuminate the waterworks and water towers and operate an electric railroad from Humboldt avenue to this place, introduced by Delegate Charles F. Kelly, was passed by the House of Delegates a short time ago.

Colorado Springs, Col.—The plant of the Colorado Springs Electric Company was badly damaged by a recent hurricane.

Crossville, Tenn.—A number of citizens have resolved themselves into a company, to be called the Crossville Electric Light & Power Company, and will apply for a charter. The company is capitalized at $2,000 and will light the streets, homes and churches.

Deshler, O.—The electric light plant here has been sold to F. Maurer of Bloomville, who has taken possession, and will overhaul the plant, add new boilers and machinery, and put it in first-class order.

Glendive, Mont.—C. H. Patterson, W. Lowe and G. Lander have filed articles of incorporation of the Glendive Electric Light & Power Company. The capital stock is $10,000.

Great Neck, N. Y.—The residents of this place and Thomaston are pleased to learn that the Arcadian Electric Light & Power Company of Manhasset, has been granted permission to extend its service to these places.

Gunnison, Col.—This place is to have a competing electric light plant, to be erected by W. H. Endner and Charles E. Meyer, who promise light, heat and power to the people of the town at a much lower rate than they are now paying.

Hughesville, Pa.—The Hughesville Electric Light Plant was recently destroyed by fire.

Irwin, Pa.—The stockholders of the reorganized Irwin Electric Light & Power Company have decided to increase their bond issue from $50,000 to $120,000, the additional amount is to be used for betterments and to enlarge the plant.

New York City.—New electric lights have been placed at the ends of all the benches in the new waiting room of the Grand Central Station. They consist of one large incandescent light surrounded by five smaller ones and mounted on wrought-iron supporting columns.

Parsons, Kan.—H. Levi lately made a proposition for parties out of town to furnish an up-to-date electric light plant if the city would give a 10-year franchise and take 70 or 80 lights at $4.80 per light per month.

Portland, Ore.—It is said the Roseburg Water Company will soon begin active work on a new electric lighting plant.

Red Lion, Pa.—The Red Lion Electric Light Company has decided to rebuild the plant recently destroyed by fire. The new structure will be supplied with all the latest improved machinery.

South Bend, Wash.—After five years of darkness, due to a heavy indebtedness, the city council has entered into a contract with the electric light company to light the streets of this place.

South Englewood, Ill.—This place is to have more electric street lights.

Sullivan, Mo.—The Hodgman Manufacturing Company contemplates erecting an electric light plant at its factory.

Sumpter, Ore.—W. H. Watt of Hailey, Idaho, will erect an electric light plant on the Hood River to furnish power for mining to cost $300,000.

Versailles, O.—Bids will be received until December 12 for furnishing materials and labor for the construction of an electric light plant in this village. Address L. C. Klipstine, secretary.

Williamsport, Md.—The electric light plant in this place is on the verge of closing down, owing to the failure of the water supply, which is obtained from a large spring near by.

York City, Pa.—The Merchants' Electric Light, Heat & Power Company has been organized by C. H. Bear, president; T. B. Loucks, secretary. The new organization proposes to apply for a charter at once for the purpose of furnishing light, heat and power within the precincts of the community and throughout this city.

Street Railways.

Birmingham, Ala.—E. F. Enslen and others are interested in a new system of electric railways to be built in this city and are forming a company for this purpose.

Blanchester, O.—Messrs. E. D. Smith, D. W. Hogan, M. V. Whitacre and others of this place are interested in a proposed electric railway from here via Fayetteville and Georgetown to Ripley.

Easton, Pa.—The Easton Consolidated Electric Company has accepted an offer of the Johnson syndicate to lease the former's entire system of electric roads in Phillipsburg, N. J., and Easton, and the lines from Easton to Bethlehem and Nazareth. In all there are about 30 miles of track.

El Paso, Tex.—The El Paso & Juarez Traction Company has completed all the arrangements to build its electric line in El Paso and suburbs. A. Mills and J. A. Happer are directors of the company.

Flat Rock, Mich.—The council of this place has granted a franchise to the Toledo & Detroit Electric Railroad Company allowing it to build a line through this village on Church street.

Ionia, Mich.—The Ionia common council has granted an electric street railway franchise to the Howard Company of Grand Rapids.

Lancaster, Pa.—The Lancaster, Willow Street, Lampeter & Srassburg Railway Company has been incorporated with $150.000 capital stock to build an electric line ten miles long in Lancaster County.

Lexington, Ky.—The Lexington Railway Company will expend about $30,000 on improvements to its power house.

New York City.—The work of equipping the Broadway, Lexington and Columbus avenue street car lines with the underground trolley system has been completed. President Vreeland of the Metropolitan Street Railway Company said recently that the electric cars would not be operated on the old cable lines for four months yet because he did not consider it advisable to test the new arrangement in winter.

Norwalk, O.—The Sandusky, Norwalk & Southern Railway Company has been incorporated with a capital stock of $400,000. The new company intends to extend the present road from its terminus at this city to Mansfield and use electric motive power. It will carry passengers, freight and United States mail.

Salt Lake City, Utah.—The council has granted permission to the Salt Lake City Railroad Company to build a double track street railway in this city to be operated by either electricity or compressed air. R. C. Naylor, city recorder.

South Orange, N. J.—The first experiment in carrying freight by trolley in Essex County is about to be tried between Orange and this place upon the road of the South Orange & Maplewood Traction Company.

St. Charles, Mo.—At a recent meeting the city council granted a franchise to the St. Louis, St. Charles & Western Railway Company to operate an electric road over certain streets of this city.

St. Joseph, Mo.—Eastern capitalists headed by J. P Gibson of Philadelphia, are said to have completed a deal for the construction of an electric railway between Kansas City and this place on the east side of the Missouri River.

Toledo, O.—This city is to be connected with Sandusky by an electric line. The Sandusky Interurban Electric Railway Company has filed with the Erie County Commissioners a petition for a franchise to lay tracks and string trolley wires from a point near Ruggles' Beach to Berlin Heights, thence to Berlinville, and from there to the county line. Mr. Woods is manager.

Whittier, Cal.—D. H. Thomas has filed with the city council an application for a franchise to operate an electric railway in certain sections of the city.

Manufacturing.

Charleston, W. Va.—The Electric Paper Manufacturing Company has been organized here with a capital stock of $5,000,000.

Chicago, Ill.—John Anderson, Charles A. Anderson and Milton Stamm, are interested in a new concern located here, and known as the Tinthoff Electric Company, which will manufacture electrical machinery and apparatus with a capital of $2,500.—The Baird-Chandler Manufacturing Company of this city has increased its capital stock from $10,000 to $50,000, and its directors from three to five .The object of the concern now is the manufacturing and dealing in electrical appliances.

East Orange, N. J.—The Morris Electric Company of New York has decided to build a factory here for the manufacture of street cars and a general line of electrical supplies.

New York City.—The Dynelectron Company has lately obtained a charter which gives it the right to manufacture and deal in electrical supplies and those of the company's invention. The capitalization of the concern is $1,200,000. George W. Angle is one of the interested parties.

Peterboro, Ont.—Manager Nicoll, of the Canadian Electric Company of this place, has, for $750,000, obtained control of the Royal Electric Company of Montreal, thereby practically obtaining a monopoly of the electric manufacturing in Canada.

Company Matters.

Baltimore, Md.—The Baltimore & Ohio Railroad Company has closed a contract with the Electric Storage Battery Company of Philadelphia for a storage battery to assist in hauling trains through the belt tunnel by electricity.

Boston, Mass—The Massachusetts Electric Companies stockholders have elected the following trustees to serve for three years: S. Endicott Peabody, Everett W. Burdett, E. Rollins Morse, Philip L. Saltonstall and Philip Dexter.

De Kalb, Ill.—The Sycamore & DeKalb Electric Railway Company, formerly of Sycamore, Ill., lately changed its name to the De Kalb County Light, Heat & Traction Company, located in this city. This company will now operate an electric light and power plant.

Plainfield, N. J.—In place of the steam cranes in use at the present time at the foundry department of the Pond Tool Works, modern electric ones are about to be substituted, together with other conveniences.

Power and Transmission.

Bristol, Tenn.—The Bristol Light & Power Company has been incorporated with $25,000 capital stock for the erection of an electric power plant in this place. B. L. Dulaney, Ed. K. Bachman, C. D. Caldwell, John H. Caldwell, of Bristol, and Col. E. J. Sanford of Knoxville, are the interested parties.

Automobiles.

New York City.—The Auto-Tool Company has been formed here with a capital of $600,000.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The capital stock of the Marietta (O.) Electric Company has been raised to $250,000.

The Plattsburg (N. Y.) Traction Company shows a net income of $2,974, in its last quarterly report.

The London County Council has decided to take steps to institute a service of electric cars throughout the English metropolis.

Contrary to general opinion very few General Electric debenture 5 per cent. bonds have been exchanged for common stock.

Westinghouse Electric recently crossed par again, and is now selling at nearly the highest point on record on the Pittsburg stock Exchange.

The New Rochelle & Westchester Telephone Company has moved its principal office from New Rochelle, N. Y., to New York City.

The "Journal of Commerce" gives the December dividend payments of industrial companies as $50,689,490, with several important payments still to be heard from.

Prominent capitalists of Toledo, O., will build an electric road from there to Defiance, going through six towns. Almost all of the right of way has been obtained.

The American District Telegraph Company, of Brooklyn, N. Y., has declared a dividend of 3 per cent., payable December 10. Books close December 3 and re-open December 11.

The notice of the New York Stock Exchange in respect to the admission of the Amalgamated Copper Company to its unlisted department states that the capital is $75,000,000, all of which is outstanding.

In Philadelphia financial circles it is believed that the recent unusual activity in Philadelphia Electric, Union Traction and United Gas stocks suggests a deal or combination of some kind involving these important properties.

The directors of the London and River Plate Bank, Limited, London, have declared a dividend of twenty per cent. to the shareholders for the year ending on September 30 last. In addition to this the sum of $200,000 is carried forward to new account.

The London Metropolitan Underground Railway Company will open bids December 1 for the work of equipping it with electric motive power. The Thomson-Houston and the Westinghouse companies are bidding and there are a considerable number of British bids.

A Brooklyn Rapid Transit stockholder says: "I feel sure that Metropolitan interests have acquired considerable Brooklyn Rapid Transit stock. There is a growing scarcity of the stock in the Street, and the time is not far distant when none can be had at anywhere near the present price level."

The Illinois State Board of Equalization is expected to impose a net assessed valuation of $1,000,000 on the Chicago Union Traction Company and consolidated companies; $600,000 on the Chicago City Railway; $50,000 on the Chicago Telephone Company, and $100,000 on the Chicago Edison Company.

A mortgage for $80,000 in favor of the John A. Roebling Company of New York against the Mississippi Valley Telephone Company has been filed with the register of deeds at Minneapolis. Minn. A statement of total liabilities that accompanies the document places the company's indebtedness at $97,000.

The shareholders of the Wisconsin Telephone Company, a branch of the Erie Telephone Company, held a meeting on November 26 and increased the capital stock of the company from $3,000,000 to $5,000,000. Of the $2,000,000 increase $1,000,000 will be expended on the underground system of Milwaukee.

The copper market is steady, and what changes there are in quotations are in favor of the producer rather than of the consumer, and yet consumption is not visibly restricted. The largest producers of copper, and consequently those best qualified to judge of future conditions, say they expect the indefinite continuance of a 17 cent price.

The directors of the Cambridge (Mass.) Electric Light Company offer to stockholders for subscription the 2,000 shares of stock, recently authorized by the gas commissioners', at $120 a share. Stockholders are entitled to the right to subscribe for four-fifths of the share of new stock for each share now held. Subscriptions will not be accepted for fractions of shares. The company will not buy or sell rights.

A report from Boston says that of the $5,298,000 General Electric 5 per cent. debenture bonds outstanding at the time the stockholders authorized an increase of stock by $4,415,000, with which to retire these bonds, it is estimated that $3,000,000 will be exchanged for stock, on the basis of one share of common stock for each $120 represented, by the principal of the bond at the time of such redemption. About $2,000,000 of the bonds, it is expected, will not be exchanged as this amount is held by trustees who paid less than par for them, and they are content to allow the investment to remain undisturbed.

The stockholders of the Port Chester (N. Y.) Street Railroad Company have filed their consent in the Register's office of Westchester County to mortgage the property of the company to the New York Security and Trust Company of New York City, as trustee, for the sum of $200,000 as security for the payment of $200,000, in bonds to be issued by the Port Chester Street Railroad Company. The bonds are to be payable in thirty years and bear 4 per cent. interest. The company has a capital stock of $300,000. The new issue of bonds is for the purpose of improving the property and extending the lines of the company in the towns of Rye and Harrrison.

EDITORIAL NOTES.

Is the Problem of Aerial Navigation Solved?

Opinions seem to be divided as to whether the problem of aerial navigation has been solved. Count Zeppelin, who, as is generally known, has been experimenting with his cigar-shaped navigable balloon near Friedrichshäfen in Germany, claims that it has, while many others, the Duke of Argyle among them, assert that the tests made by the German inventor signify little or nothing.

Immense sums of money have been spent during the past one hundred years by enthusiastic inventors in trying to devise a body that would travel through space as a ship travels through the sea. It was early ascertained that the principal difficulty did not lie in lifting the mechanism from the surface of the earth, but in directing its course when suspended in the air. When the aeroplane was tried, the weight of the necessary machinery to guide and propel it against a moderate breeze, made it impracticable, while with the balloon the necessary weight could be raised, but the apparatus was too bulky to be driven or guided against the wind—at least until Count Zeppelin conceived the idea of a cigar-shaped balloon ship.

In the experiments that have been made in this line electricity has played an important part, many believing that when the use of the electric current became perfected, the problem of what might be termed aerial propulsion would be easy of solution. Such proved, however, not to be the case, for the same reason that ocean going steamers are not electrically driven—namely, that the power derived was too small for the weight which it was necessary to carry.

By the use of benzine motors, exploded by electric sparks, Count Zeppelin has succeeded in propelling his 420 foot balloon ship against a moderate breeze and has also succeeded in making it perform evolutions, such as turning in a circle, twisting, rising and falling. In a recent trial the airship traveled six miles with the wind, which was blowing about ten miles an hour, and then turned and without rising or falling from the stratum of air in which it was in, came back at a fair rate against the breeze. Count Zeppelin, as previously stated, considers the problem of aerial navigation solved, and expressed a belief that with a few improvements his ship will be capable of a speed of thirty miles an hour. On the other hand the Duke of Argyle, who is an authority, is reported as saying:

"I do not think that man can overcome the natural laws that condemn all buoyant bodies to an inertia that makes them useless. They must go with the medium in which they float. They cannot resist it, seeing they have no fulcrum to act on. . . . My own belief is, that if we are ever to navigate the air it must be on the mechanical principles which nature has adopted in her glorious and exquisite mechanism of avian flight."

This may possibly be so, but it cannot be gainsaid that Count Zeppelin has succeeded in driving and guiding his ship against the wind, a thing heretofore deemed well nigh impossible. We navigate the sea, and yet our ships are not propelled after the plan of fishes, and there would therefore seem to be no reason why we should not some day travel through space in the manner suggested by the German Count.

Telegraphs and Telephones at the Paris Exposition.

Mr. John Gavey, the engineer-in-chief at the General Post Office, London, has reviewed the principal telegraphic and telephonic exhibits at Paris in a paper with the above title, which was read before the Institution of Electrical Engineers on November 22. The Exhibition catalogue included in Class 26 "Telegraphs, Telephones and Phonographs," and Mr. Gavey dealt with the subdivisions in this order, but only dwelt on those which showed considerable novelty, or which illustrated the progress made during the last decade, this course being preferable to attempting an exhaustive description of the class as a whole. There were three distinct systems of telegraphy deserving special attention, each "exhibiting considerable merit from the scientific point of view, although possibly they may be unequal from the practical standpoint." They are designed either with a view of increasing the amount of traffic which can be carried by a telegraphic circuit, or of abolishing the transcription at the receiving instruments necessary with Morse methods; but they are based on different principles.

Rowland's multiplex system, exhibited at work by the Rowland Telegraphic Company of Baltimore, Md., was an apparatus admitting

Digitized by Google

of eight messages being sent simultaneously, four in each direction. The apparatus was stated at Paris to have given satisfactory results over 600 miles of actual line in America.

Mercardier's multiple system, exhibited by M. Ernest Mercardier of Paris, was said to transmit 24 messages simultaneously over one circuit, 12 in eaeh direction. It is based on the harmonic system of telegraphy, one form of which was devised years ago by Elisha Gray. Mercardier's method, however, is not a copy of Gray's, as by the use of telephone receivers and transmitters combined in various ways, he has designed an absolutely independent method. As transmitters, Mercardier uses electrical vibrating reeds of a well-known character, and as receivers he uses a combination of a telephone and a microphone, the latter sending out a powerful series of undulations into the local circuit, these undulations being selected by suitably designed telephones, which only respond to the vibrations to which they are tuned. The method, therefore, is a Morse method pure and simple, in which, so far as the operating is concerned, the telegrapher uses a Morse key for signaling, and the receiving telegrapher uses telephones as sounders. Mr. Gavey learned at Paris that the Mercardier apparatus had, in the course of recent trials, worked satisfactorily between Paris and Bordeaux, but it required a metallic loop for thoroughly satisfactory working.

The third system was that of Messrs. Virag and Pollak, whose photo-autographic telegraphic apparatus was shown in the Hungarian section.

The author then turned his attention to the telephone section of the subject. He found that the advance in telephonic practice has, on the whole, been greater than in the branch of telegraphs devoted to the transmission of public messages. The invention and perfection of the manufacture of dry-core paper insulated cables has resulted in the more important of the telephonic administrations, both in the Old and New Worlds, undertaking the substitution of metallic for earth circuits for telephonic intercommunication. With the means at their command at an earlier period telephonic engineers were practically restricted to overhead work at their large exchanges, and although they all realized the disadvantage of earth circuits, few of them could face with equanimity the doubling of the huge number of overhead wires necessary for metallic loops. Now a dry core cable which will serve 200 subscribers may be drawn into a 3-inch pipe, and in the course of a few short years an earth circuit telephone will be a thing of the past. Not only has this improved the subscriber's circuit, but it has led to the introduction of improved telephones and improved switching arrangements, also to enlarging the number of subscribers connected to the central switches, which has brought about improved methods of automatic signaling.

Mr. Gavey proceeded to refer to the exhibit of the Western Electric Company, illustrating the central battery telephone switch, a system which is being rapidly extended throughout the whole of the United States, has been adopted by the British Post Office in London, by the National Telephone Company in some of its centers, and by the Belgian administration in Brussels.

Mr. Gavey had on the lecture table a set of Postel-Vinay switches which have been recently introduced at the newest of the Paris exchanges at the Avenue Breteuil. Their most striking feature is their remarkably small and well-designed automatic indicator, which can be placed immediately over the jack for working the junction circuits. Mr. Gavey expressed the opinion that signaling lamps are on the whole preferable to electro-magnetic indicators.

In wireless telegraphy there were four exhibits, viz.: (a) An illustration, by means of coils, of the Post Office electro-magnetic method originated by Sir William Preece; (b) M. Ducretet's Hertzian system, which is understood to have been designed by him in conjunction with M. Popoff, the Russian inventor, and which has been adopted in the French and Dutch navies; (c) the Slaby and D'Arco system of the Allegemeine Elektricitäts Gesellschaft, Berlin; (d) the Poulsen microphonograph. The "Telephone Hirmondo," which provides news and musical transmission alone, but without telephone intercommunication, in the city of Buda-Pesth, was also briefly referred to.

* * *

Street Railway Mergers. During the past week there have been several large transactions in street railroad lines, notably the one in New Jersey, where the trolley roads in Elizabeth, Rahway and Plainfield were consolidated with $3,000,000 capital. The concentration of electric railways under one control naturally creates a stir in financial circles, but the New York "Financier" says there is nothing especially new in this as street railway absorption has been going on for some years, resulting in corporations like the Metropolitan system, the Brooklyn Rapid Transit system, and others of almost similar magnitude. More than one banking house in New York can trace the foundation of its wealth to street railway consolidations, and as the business offers almost limitless possibilities, there is no question that great profits will be made in the future. Up to now the process of merger has been applied to systems in prominent cities only, but as these have been for the most part pre-empted, attention is being turned to smaller centers. When it is recalled that there is scarcely a city of 5,000 population in the United States without its electric railway, and that in many places ranging from 10,000 upward, two and more independent lines are found in operation, the opportunity, it will be conceded, is an attractive one to the street railway specialist. In many instances towns lie so closely together that a central plant is capable of furnishing both with power, and for that matter with electricity for public and private use. The operation of small plants, as generally conducted, is wasteful in the extreme. Not only that, but the service to the public is limited, and by reason of lack of transfers, costly to both interests. The street railway specialist in his work of eliminating the expenses and inviting larger revenue through better service at more frequent intervals over a longer distance, performs a real service, both to the shareholders and the community in which he is working. If he can increase gross profits from one fourth to one-half, at the same time effecting an actual economy in operating expenses, he is fully entitled to all the pay he receives in the shape of new stock or cash. The community has no reason to complain, for in every instance it gets better service, longer rides and quicker transit. The secret of success in American manufacturing industry is the ability to produce cheaply by employing the best and highest paid labor in the world. The same rule holds true in street railway and public enterprises of like character, for economy in operation, on the standard of most efficient service, yields dividends. It would be impossible, naturally, to say how many hundreds of thousands, or millions of dollars are being wasted annually in this country through unnecessary duplication of expense in street railway operation, but the total is a heavy one. The men who are engaged in reducing this waste deserve success. The field is one that appeals particularly to young men who have acquired a thorough and technical education in electricity.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The American Society of Mechanical Engineers is now holding its meeting in this city at 12 West 31st street. The convention will adjourn on Friday, December 7.

There is considerable talk in England regarding the adoption of Marconi's system of wireless telegraphy by the Post Office, or, in other words, the Government. The principal stumbling block is the price to be paid for the use of the system by the authorities.

The Lehigh Valley Railroad is extending its system of electric automatic switches to its entire main line and the principal branches.

Our London correspondent informs us that the British Westinghouse Electric & Manufacturing Company, Ltd., is to bring a bill before the next Parliament enabling it to undertake the electrical equipment of the Metropolitan and the Metropolitan District Railways and to suspend the running power of the other railways (operated by steam locomotives), which make use of the underground tracks, during the time occupied in effecting the conversion from steam to electrical working.

An inquiry for what it is claimed will constitute nearly $100,000 worth of electrical machinery has been received from Italy by an engineering firm in this city. A cable reply is requested specifying the earliest delivery possible. Upwards of $50,000 of such machinery has been sent from this port to Genoa recently. Italy is one of the most advanced electrical engineering countries of Europe.

The Illinois Central is planning a change in the equipment of its suburban lines in Chicago from steam to electricity, and a large portion of the $6,000,000 which will be spent in improvements will probably be used for this purpose. The road recently increased its capital stock by this amount, and the report was current lately that this change in motive power was to be established at an early date.

Reports to the chief signal officer from Manila indicate that the War Department has made an important discovery in connection with submarine cable work in tropical waters. One of the War Department cables that was shipped to Manila, and put down for interisland communication, happened to be of the rubber insulated variety. The English cable experts

Digitized by Google

in the islands predicted its speedy destruction by the toredo, a submarine boring worm which eats everything short of railroad iron which may be submerged in the water. The English cable, with gutta percha insulation, resists the attack of this insect for only about a year, and it is necessary to insert in the cable armor a thin continuous wrapper of sheet copper to prevent the toredo from boring clear through to the conducting wires and short-circuiting the cable. This copper protection adds considerably to the expense of the cable, without adding to its efficiency for telegraphic purposes. It seems, however, that the American cable, with its rubber insulation, which has been down for two years, is still in good working order, an important argument in favor of the use of rubber over gutta percha, aside from the fact that rubber is the cheaper insulation of the two. Colonel Allen, chief signal officer in the islands, has advised General Greely that the cable staff of the signal service is at present organized on a very effective footing, and will be able to lay practically any amount of cable the department may see fit to ship to Manila.

SIGNOR MARCONI, according to a recent report, has practically solved the question of ocean transmission by wireless telegraphy, and will soon be able to use his system across the Atlantic.

F. D. PEARNE, who has been working for the Iowa Telephone Company in Le Mars, Ia., is the patentee of a telegraph typewriter from which great results are expected. The machine, it is claimed, will enable a man to write on a typewriter connected with telegraph wires in an office in one city and reproduce almost instantaneously the matter in copy in an office at another point.

PROGRESS on the New Hamilton Otto Coke Company's plant north of Hamilton, O., has been so rapid that it is now practically certain that the company will be making coke by the middle of January. An interesting feature of the new plant is its power apparatus. All of its hoisting and coke smoking machinery will be driven by electricity, furnished by the company's own plant; motors aggregating 300 horse-power are already being installed.

THE Governor of the island of Crete, in the Mediterranean, is inviting bids for quite a number of railway bridges. Since Prince George of Greece has been appointed Governor of Crete the country has made progress in every respect. Canea, the capital, is now to be lighted by electricity.

A CORPORATION has been formed in this State to run coaching parties to and from Long Island towns in automobile drags and a trial trip of a nine seated vehicle will soon be made. Electricity will be the means of locomotion. The American Bicycle Company, 941 Eighth avenue, New York City, will supply the automobiles, but R. M. Barwise, the manager, refused to give the name of the new company or its capitalization.

A STOCK-YARD firm in Chicago runs a miniature electric trolley system, which is used to haul meats to the various departments of the packing house. The line is complete in every detail, with overhead wires, trolley cars, trailers, switches, curves, and all the other things that go to make up a trolley system. It is built upon the broad gangway, fifteen feet from the ground, which connects the second floors of several of Armour's big buildings at the stock-yards, so it is really an elevated road, the smallest in the city. The motor cars with a little trolley pole jutting up to the wire are just big enough to contain the controller box and the motorman, and the trailers in which the meat is hauled are open boxes of steel similar to the old-fashioned trucks which were propelled by hand. They are attached to the motor with little coupling pins. The tracks have switches at the proper points to divert the little trains to one building or another as may be desired.

THE town of Boulder, in the new gold fields of West Australia, was recently equipped with generating sets for lighting and power purposes and electric motors for operating hoists, etc., in the mines.

THE electrical development at Ottawa, Canada, although of comparatively recent date, has been most rapid. In 1887, the Chaudiere Electric Light & Power Company was organized and was practically the beginning of the large system which now supplies Ottawa and Hull with electricity for lighting and power. The first dynamo had a capacity of 250 incandescent lights. The dynamos to be installed in the new power house of the Ottawa Electric Company now under construction, have a capacity of 15,000 lights each. In 1895, an amalgamation of the Chaudiere, the Standard and the Ottawa Companies was effected, under the name of the Ottawa Electric Company, whose business has developed enormously until to-day it has installed 700 arc lights and about 100,000 incandescent lights, being a larger number, per capita, than any other city in the world. The history of the Ottawa Electric Street Railway Company is very modern, but its growth has not been less remarkable than that of the lighting interests of the city. Only ten years ago the gross annual receipts of the horse railway company of Ottawa were $27,000, and the number of passengers carried in a year were 65,000. The receipts of the Ottawa Electric Railway Company this year, will be over $300,000, and the number of passengers carried will exceed 8,000,000. This electric railway began its operation with about ten miles of track, and to-day it has forty-two miles.

CONSUL-GENERAL PATTERSON, at Calcutta, India, says in a report to the State Department at Washington, D. C., that the Calcutta Tramway Company, Ltd., is preparing to change its lines from horse power to electricity and the contract for the power station, has been given to Messrs. Dick, Kerr & Co., Ltd., of London. The first shipments for the plant are expected to arrive this month. Mr. Patterson says: "I have answered many letters from our various electrical companies relative to the use of electricity here, calling their attention to the proposed change in the tramway company's lines, and believe that, with proper efforts on their part, the contract might have been secured, as Americans are now competing successfully with the English companies even in London. Electricity is now beginning to be extensively used in Calcutta for various purposes, such as lighting, fans to take the place of punkas that were pulled by coolies, for driving machinery, etc., and there is an opening here for the sale of electrical machinery and goods, which our manufacturers should take advantage of. I would advise correspondence with Messrs. Kilburn & Co., here, who have an electrical plant and are furnishing electricity and electrical machinery and goods; also, with the following named firms in Calcutta, who are dealers in such machinery and goods, viz.: Osler & Co., Octavius Steel & Co., and the Calcutta General Electrical Company. All machinery is now entered duty free in India, but there is a duty of 5 per cent. ad valorem on goods. There is a direct line of steamships between New York and Calcutta, but a cheaper freight on machinery and goods not required for immediate use would be by sailing vessels via the Cape."

IT is now stated that the recent Tarrant fire in this city was not of an electrical origin. That such would prove to be the case has been our opinion all along. People are too prone to ttribute every fire that breaks out to defective insulation in an electric light or power wire.

THE first annual meeting of the Illinois State Electrical Association was held in Champaign last week. There was a large attendance and a number of interesting papers were read.

OF recent years nearly every town is provided with an electric generating plant and frequently the wires are strung along country roads from town to town. This fact has led a man named McNair to attempt the use of electricity on the farm. He has devised a curious pen some 15 feet square, built of wire and mounted on broad, flat wheels. This pen is designed to run in any pasture, even though it be hilly. Wires connect it with a small motor stationed at one side of the pasture, this in turn being connected with the electric wires from which power is derived. A turn of the button and the pen slowly creeps across the field. That is the essence of the invention, and simple enough it seems. A machine of this type is being experimented with at the Agricultural Experiment Station of Michigan, at Lansing. Two lambs and part of the time an old ewe have been pastured in the pen during the summer. The field is planted with lucerne, growing thick and heavy. The pen is so arranged that it crawls the full length of the pasture in one month, traveling about two feet an hour; at the end of this time it is switched around and travels back again. As it moves the sheep eat every bit of the fodder, eagerly cropping next the forward side of the pen as it runs over new ground. A bit of canvas duck is hung over the corner of the pen so that the sheep may be well sheltered, and curious as it may seem, they have become so accustomed to the moving of the pen that when they lie down to sleep they snuggle up close to the forward end of the pen so that they may lie as long as possible without being disturbed by the rear end of the pen as it creeps toward them. When the pen has passed, of course, the lucerne that has been cropped by the sheep immediately grows up again and by the time the pen has made its monthly circuit the pasture is again in good condition. The advantages of this electrical pen lie in the fact that the sheep are kept from running over, half eating and tramping down a large amount of pasture, and it keeps the sheep quiet, so that they lay on flesh rapidly.

"Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 4.

PRIMARY BATTERIES.

Current Produced by Chemical Action.—Any combination of metals or substances acted upon by acids so that the chemical action will produce electrical action may be called a primary battery,

When wood is burned the carbon of the burning material combines with the oxygen of the air, and heat is given out as a result of the chemical combination, which we call combustion. In a similar manner if a piece of zinc be placed in some sulphuric acid, the acid combines with the zinc and as a result of the chemical combination heat is given off. Of course heat represents a certain energy or capacity of doing work. It has been discovered that under certain conditions the energy in this manner represented by chemical action is productive of electrical action, and taking advantage of this we get electric batteries.

When two different metals are placed so they do not touch each other and immersed in a liquid which will attack them chemically, one of these plates will become a positive pole and the other negative, to a current of electricity that will be produced by the chemical action and be caused to flow over a circuit which is connected to the exposed ends of the plate. A jar or vessel containing two plates thus immersed in a solution of acid or acidulated water is called an electric battery cell, and the plates are called the electrodes of the cell. It is customary to speak of the electrode from which the current is flowing as the positive pole and the other electrode is known as the negative pole, the difference of electrical pressure between the two elements is known as the electro motive force or voltage of the battery, that is, the current will leave the positive pole at a certain pressure or force, consequently will have the power of doing work in a circuit which is connected to the two plates of the cell. The current of electricity produced in this way not only flows from the positive plate to the negative plate through a circuit, but also flows within the cell itself from the negative plate to the positive one, consequently the negative plate will be known as the positive element of the battery while the positive pole is known as the negative element. We might illustrate the action of an electric battery cell by saying that the cell performs the same function to the electric energy set in motion, as a pump would that had its discharge pipe connected to the point where the water is taken in, to the flow of water in the pipe. Now if the pump be set in motion it will force the water to circulate through the pipe and also within itself, the pump acting as the motive power of the circuit. Just so in a battery, electrical action is produced by the cell and the chemical action is the motive power of the circuit.

There are a large number of different styles of cells used and the combination of elements are as varied. We will not attempt to describe or explain very many of these, but will take up in detail a few of those most commonly known and used, so that the reader may get a general knowledge which will be of value to him in the care, use and purposes of them. The strength and direction of the difference of electrical pressure between the poles of a cell depend upon the material used for the plates and the nature of the liquid. Take for an example, if copper and zinc be used as the plates and sulphuric acid as the liquid the electromotive force or pressure produced will not be quite a volt and the copper plate will be the positive pole of the cell. In a battery of this description a vigorous chemical action will go on at first but will gradually decrease in intensity and finally will appear to stop entirely. This may be plainly shown by having the current do some work, for instance, if an electric bell were placed in the circuit it would ring very loudly when first connected, but would soon weaken and after a short time would cease to ring altogether; if we then examine the plates a layer of bubbles will be found covering the surface of the copper, these bubbles are composed of hydrogen gas which is generated by the chemical action that was going on in the cell. The effect of this condition is twofold. In the first place the existence of these hydrogen bubbles causes a counter or opposing electric pressure in the battery opposite in direction to that of the regular action of the cell and thus the effective pressure of the cell is reduced. This layer of bubbles also presents a high resistance to the flow of current, for you remember we said that the current flows within the cell as well as in the circuit to which it is connected. A battery that is made inactive by the above condition is said to be polarized and the effect is called polarization.

In order that a battery may be capable of doing efficient continuous work some way must be devised to keep it from polarizing, or in other words keep it depolarized. This can be accomplished in any one of three different ways. First, by mechanical action. Second, by absorbing the hydrogen by chemical action. Third, by electro-chemical means whereby the hydrogen condition will be exchanged for a metal which will be deposited upon the positive plate.

The method of depolarizing by mechanical means is that the hydrogen bubbles be cleared from the positive plate as rapidly as they are deposited upon it. This can be accomplished by blowing air into the liquid or continually stirring it, which method however is not practical. If the surface of the plate be roughened the bubbles will not adhere so closely and a great many of them will come to the surface and vanish. This idea was used some time ago to accomplish this purpose, but was not very successful and has since been replaced by more modern and practical methods.

In the second way of absorbing the hydrogen, a substance can be added to the liquid which will combine with the hydrogen as rapidly as it forms and polarization prevented. A number of substances can be used for this purpose but the ones most commonly employed are bichromate of potash, dioxide of manganese and nitric acid. A battery that we may use as an example of this condition is the one commonly known as the bichromate cell. It is a carbon and zinc battery the liquid of which is composed of sulphuric acid which has dissolved in it bichromate of potash. When chemical action is going on in this cell the polarization is prevented by the direct combination of the hydrogen which forms with the bichromate of potash. Copper is not used for the positive plate in this style of cell, but is replaced by carbon, because bichromate of potash will attack and destroy copper; this battery is sometimes known as a "plunge battery" because the zinc is not allowed to remain in the cell for the liquid acts continually upon it and eats it up.

In the well known Leclanché battery, dioxide of manganese is used to produce the depolarizing effect and is generally broken up into small pieces and placed in a porous cup with the positive plate or carbon. Sal-ammoniac dissolved in water is used as the liquid in this style of battery and a zinc pencil as the negative pole. Sometimes the dioxide of manganese is powdered and mixed with some adhesive liquid such as shellac for instance and then formed into bricks which are placed on each side of the carbon element secured to it by rubber bands. This you will recognize at once as the well known and familiar "prism" battery.

These cells just described are known as open circuit batteries, by that we mean cells which it would not do to have working continuously and are only for such purposes as ringing door bells, electric gas lighting, etc.

If we require a continuous current, such as for telegraph use, a style of cell is used that is known as a closed circuit battery, that is, one in which the circuit may be continually in operation. A battery of this type is the "gravity" cell.

To set up such a cell copper plates are placed in the bottom of the jar and then covered with sulphate of copper, often called blue stone, the jar is then filled with water and a zinc suspended from the side of it so that it will remain near the surface of the solution although covered by it. When hydrogen gas is generated in a cell of this description it will travel toward the copper, and combine with the copper sulphate solution separating copper from it, and depositing it upon the copper plate, which will consequently be kept clean and in good working condition. This is an example of the third method of depolarization whereby the hydrogen is practically exchanged for a metal which is deposited upon the positive pole. The name "gravity" is given to this cell because the copper sulphate solution remains at the bottom of the jar while the zinc sulphate formed by the action of the cell will be at the top, whereas gravity keeps the copper sulphate solution at the bottom of the cell because it is much denser and of greater weight. To start one of these cells in action rapidly a small amount of diluted sulphuric acid may be poured in it to more readily start the chemical action.

Some chemical action by which zinc is wasted goes on in nearly all battery cells when the circuit is open. This can also occur when the cell is being used for producing electrical energy without adding to or helping the action which produces the electro-motive force of the battery. Chemical action of this nature is called local action. It is very often caused by metallic impurities in the positive element or zinc, which forms with the pure zinc little individual electric batteries, the action of which causes the zinc to be eaten away in spots. Another condition which may also cause local action is a difference in the density of the liquid in the cell. An example of this is often noticed where the zinc may be almost eaten apart near the top of the solution while the lower end of it may still remain near its original size.

Digitized by Google

If the surface of the zinc be amalgamated by dipping it in a dilute acid and then rubbing it with mercury the impurities in it will be covered while the pure zinc will be brought to the surface in a sort of paste form caused by its combining with the mercury. This will to a great extent prevent local action or a waste of energy.

Article No. 5 will be entitled Secondary or Storage Batteries.

ANSWERS TO QUESTIONS OF LESSON NO. 3.

First—5 ohms.

Second—100 volts.

Third—5 amperes.

Fourth—55,000 watts. Between 73 and 74 hp.

THE OUGRIMOFF "ELECTRIC CALORIFACTOR."

Translated from "L'Electricien," Paris, for ELECTRICITY.

Mr. Ougrimoff, a professor in the Imperial Polytechnic School of Moscow, Russia, exhibited a curious apparatus at the Paris Exposition, which he calls an "Electric Calorifactor." It is a kind of steam generator in which the necessrry heat for vaporizing water is produced by an electric arc which advantageously replaces fuel.

This heater is a remarkable invention on account of its simplicity and its many uses, for it is capable of many applications, especially in factories supplied with electricity generated from water power.

It is generally known that sugar refineries, distilleries, chemical works, and other concerns using electricity as a motive power, are often obliged to install steam boilers to meet the various requirements of heating. In such places an electric steam generator may be very useful, especially when the price of electric energy is extremely cheap, as is the case in shops supplied with current from water power.

The Ougrimoff heater employes a powerful electric arc enclosed in a tube to transform electric energy into heat. It requires little space, as furnace, flues and chimney are replaced by a very simple tube.

As may be seen in Fig. 1, which shows the apparatus in vertical section, the heater is in the form of a vertical cylinder furnished with a closed cast tube extending through the center, in which is formed an electric arc between a carbon, electrode B, and powdered graphite which fills the bottom of the cast metal receptacle C and seals the lower portion of the heating tube. The arc is wholly enclosed to prevent the admission of air when the heater is in operation. This arc requires from 60 to 100 volts.

The upper portion of the tube is closed by a solid cover A, through which a screw carrying the carbon holder penetrates and which is electrically insulated from the main body of the heater by a suitable packing.

Powdered graphite is employed as a negative electrode for the double purpose of protecting the metal portion of the tube against the very high temperature produced by the arc and also to serve as a durable resistance when the heater is in operation.

The resistance of the powdered graphite when cold, is sufficient to prevent a short circuit when the two electrodes are brought together in starting the arc, and its resistance gradually decreases as the temperature increases.

The negative wire is attached to the body of the heater, and the carbon rod B is the positive pole. This disposition is necessary to obtain good results and keep the powdered graphite scattered or spread over a large space and thus protect the inner side of the tube and also to give sufficient resistance at the time of starting the arc. While the arc is burning additions are constantly being made to the cup of powdered graphite C from the positive electrode B. With an arc of 60 amperes at a pressure of from 60 to 80 volts, the quantity of powdered graphite deposited is about two grains per hour; a quantity quite sufficient to compensate for the loss due to combustion in the arc of the graphite forming the negative pole.

The arc does not require any great precision in regulation during its operation. What little adjustment is necessary can be done by hand or by an automatic arrangement.

When the apparatus is first started the gas contained in the tube becomes warm and expands.

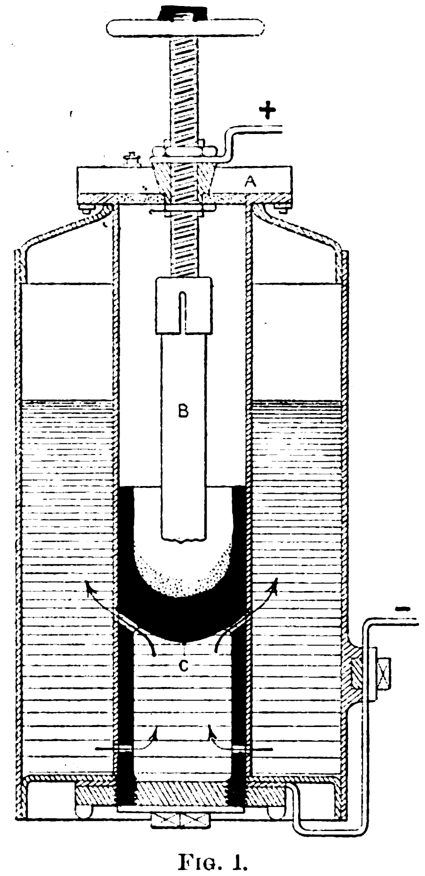

Fig. 1.
Vertical Section of Ougrimoff's Electric Heater.

Means are provided to allow of its escape through a small valve placed in the insulating material of the cover and so arranged as to prevent outside air from entering.

The heater exhibited at the Paris Exposition was 40 cm. high, 18 cm. in diameter, and consumed from 6 to 10 kw. per hour (100 amperes at 60-100ths volts). It furnished steam at a pressure of 7 kw. per square centimeter, with an efficiency of 98 per cent.

A comparative example will permit of a better understanding of the merits of the electric heater over the ordinary boiler. Let us consider a case where it is required to bring liquid to a boiling point situated at some distant point in the factory, away from the ordinary boiler. We may estimate the efficiency of the apparatus at 60 per cent., the boiler at 65 per cent., and finally the conducting pipes at 92 per cent. Under these conditions the final output of energy in heat units at the point of utilization will be

$$0.60 \times 0.65 \times 0.92 = 0.35,$$

or 1 kilogram of coal of average quality burned under a steam boiler will produce at the distant point

$$4,500 \text{ calories} \times 0.35 = 1,575 \text{ calories.}$$

Admitting that the coal costs 42 francs ($8.40) per ton, comprising the wages of the help, 1 kilogram will cost 4.2 centimes (.84 cent) and each calorie utilized will cost 0.26 centime (.052 cent).

With the electric boiler, figuring the price of electric energy at 1.5 centimes (0.3 cent) per kilowatt hour (which corresponds to the factory rates at Niagara) the price of a calorie is easy to calculate.

$$1 \text{ kilowatt hour} = 0.24 \times 3,600 = 864 \text{ calories.}$$

Admitting an efficiency of 98 per cent. for the electric boiler we can figure 850 calories as costing 1.5 centimes (0.3 cent), which makes the price of a calorie 0.17 centime (.03 cent).

With a steam boiler the price is 0.26 centime (.052 cent), giving a difference in favor of the electric boiler of 0.09 centime (.018 cent) which gives a saving of 33 per cent.

We may then consider Mr. Ougrimoff's apparatus to be a new application of electric heating capable of a great development, for it dispenses with fire boxes and chimneys, takes up less room, and is more easily shipped and installed and also lessens the fire risk.

It is easy to see that this little piece of apparatus is the starting point of a series of improvements which will finally permit of a more economical and rapid generation of steam in boilers of large sizes.

THE RITCHIE TELAUTOGRAPH.

The following description of the Ritchie Telautograph, the invention of Mr. Foster Ritchie, appears in the "Electrician," London. As will be seen, the principle is practically the same as that of Prof. Elisha Gray's instrument, which was exhibited quite extensively in this country some seven years ago, excepting that the modus operandi has been improved upon.

A very fair idea of the working of the instrument may be obtained from an examination of the illustrations here given. Fig. 2 shows the principle on which the instrument is based and Fig. 1 is a diagram of the connections. The pen is fixed at the extremities of two links, A and B, which are fixed to the arms of two otherwise independent rheostats, C and D. Each of these is connected through the battery to one of the two lines and has a total resistance of 7,000 ohms, divided into 496 steps. One of these rheostats is shown by the side of the instrument in Fig. 4. Thus currents, varying in magnitude with the position of the pencil, are sent along the two lines which connect the sending and receiving instrument. The receiving part of the instrument consists of two large d'Arsonval galvanometer movements, with strong controlling springs to ensure constancy. The spindles on which the moving coils are fixed are connected to a link motion corresponding to that of the transmitter part of the instrument, and move a pen along a similar piece of paper.

Having indicated the general principle on which the instrument is based, we now come to its constructive details. As is seen in Fig. 1, a battery is placed at each end of the line, these two batteries being normally in opposition. Before starting to write, the operator takes up the pencil, seen in the general view of the instrument, Fig. 4, and, with the point of it, pushes back a lever at the left of the lower

Digitized by Google

or transmitter part. This works a mechanical grip, which clutches the paper and moves it forward about three-fourths inch, and at the same time operates a switch reversing the home battery, cuts off the receiving part of the home instrument, and connects up the transmitting portion. A further movement of this lever momentarily opens up the circuit of the home battery, the reason for which will be explained presently. The paper is 5 inches wide, and a length of about 2 inches is exposed at one time. During the motions of the pencil on the paper, currents varying in strength are sent along the lines F and G, returning in each case by the earth.

The lower part of Fig. 1 represents the transmitting part of the home station, and the upper part the receiving part of the distant station, but the complete instrument in each case is made up of a transmitter and a receiver. H and K are the coils of the d'Arsonval

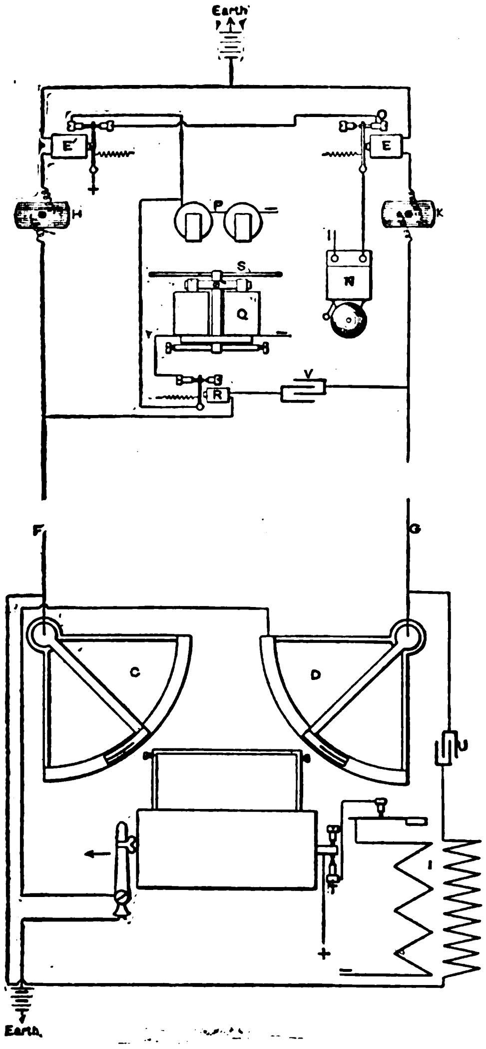

Fig. 1.—Diagram of Connections.

galvanometer movements, these movements being also seen distinctly in Fig. 4. The coils have about 600 turns of silk-covered wire impregnated with shellac varnish, and only the coil revolves, the cylindrical piece of iron at its center being fixed. The magnets are electromagnets excited by the local battery. An interesting feature of the instrument is that, instead of extreme delicacy being attempted in the construction of these movements, the reverse is the case. Twenty-four volt secondary batteries are employed at each end of the line, and the rheostat naturally forms the greater part of the resistance in the circuit, so that fairly strong currents, telegraphically speaking, flow through the coils. Added to this that the magnets of the d'Arsonval system are highly magnetized, it is seen that considerable mechanical forces come into play, so that the controlling spring attached to the moving

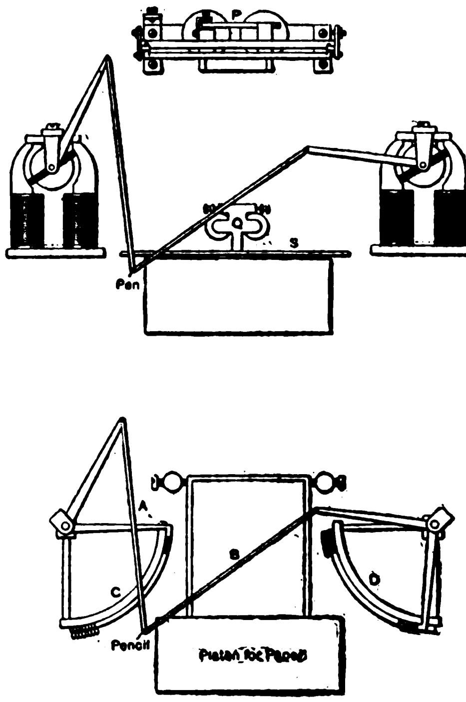

Fig. 2.

coil is strong, and, as a matter of fact, so strong that the spindle of the moving coil is merely held between centers, jewels being unnecessary. Thus the motion of the coil is decisive and dead-beat, and, moreover, adjustment is easy and the whole mechanism is substantial.

After traversing the moving coil on its way to the distant battery the current passes on either side through a relay E' and E. These relays are so adjusted that the weakest current (sent when the pencil is at the top left-hand corner of the paper) just suffices to cause their armatures to be attracted. When the current is momentarily interrupted by moving the paper-shifting and starting lever, the relay E' drops back. This causes the current normally flowing through the paper-shifting magnets P to be momentarily interrupted, and the release and re-attraction of the armature of P actuates the grip which moves on the paper. The

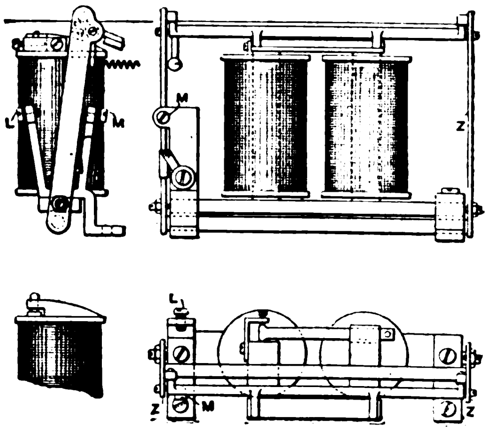

Fig. 3.—Details of Paper Shifter.

details of this paper-shifter are shown in Fig. 3, which is more or less self-explanatory. The whole frame Z rocks backward and forward when the current through the coils is interrupted and re-made. L and M are merely stops. The relay E is for the purpose of signaling. A press-key on one side of the transmitter (not shown in the diagram Fig. 1) on being depressed breaks line F and puts line G to earth. This causes the relay E' to release its armature and the relay E to make a contact at O, so that the local circuit of the bell N is closed and the bell rings. It should be mentioned that to avoid a multiplicity of lines

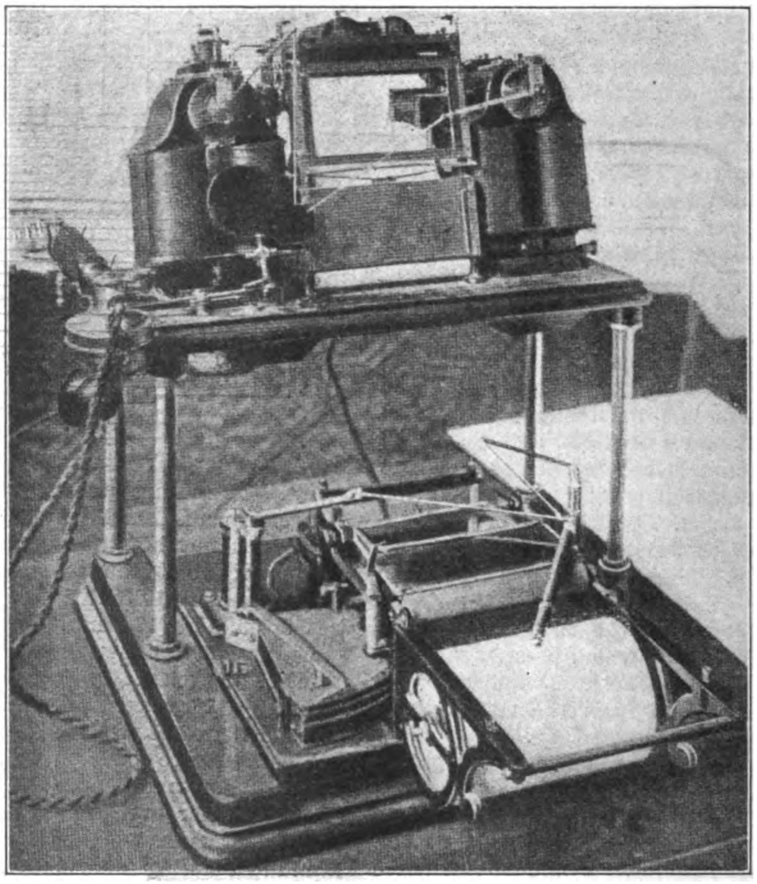

Fig. 4.—General View of Telautograph (cover and paper removed).

in Fig. 1 all the wires leading to the battery are not shown but some are broken off and + or — marked against them.

We now come to the ingenious device by means of which no characters are written on the paper at the distant station unless the pencil is actually pressing on the paper at the transmitting end. Motions of the pencil are transmitted to the pen, but the latter does not touch the paper until the pencil does. Normally the "pen-lifting" magnet Q is excited by the local circuit, the armature of the relay R being against the left-hand stop. This magnet Q raises the pen from the paper by slightly moving the cross-bar S in a horizontal direction away from the vertical paper. When, however, the pencil presses upon the platen on which the paper is stretched, it puts the battery in contact with the screw T, which closes the primary circuit of a small induction coil I whose hammer vibrates. Thus a vibratory secondary current is transmitted to line G through the condenser U, and passes to the receiving end, through the condenser V, and energizes the relay R. This breaks the local circuit of the magnet Q and allows the pen to fall back on the paper. The vibratory current returns by the line F, and not by earth, so that it does not affect neighboring telephone circuits. The circuit KEE'H has fairly high self-induction, and the relays E' and E are not influenced. It is also noticed that the local current reaches Q through the secondary contacts of the relay E' as well as of the relay R, so that when the apparatus is not in use and no current is flowing through E, no current is being wasted in the pen-lifting magnet. The same applies to the magnet P.

On finishing his message, and before laying down his pencil, the operator must press down, with the point of the pencil, a small plunger key on the left of the instrument to reverse the home battery so that it opposes the distant one, and to connect up the receiver to line instead of the transmitter. This switch is not shown in the diagram. The action of depressing this plunger also opens a local bell circuit, which is, moreover, opened at another contact so long as the operator's arm is resting on the desk. If, therefore, he retires from the instrument without switching off by depressing the plunger key, the bell circuit is closed and the bell rings until the omission has been remedied.

A telephone is employed in connection with the instrument. When the telephone is on its hook, the writing telegraph is connected to the lines in the manner already detailed, and on removing the telephone the writing telegraph is disconnected and the ordinary telephone connections substituted. The telephone is seen to the left in Fig. 4.

As already mentioned, a 24-volt secondary battery is employed at each end, and with this the instrument is found to work well on a line up to 300 ohms resistance. The resistance of each of the moving coils is about 185 ohms, and of the relays only about 20 ohms each.

An interesting detail is the pen employed. This resembles a tiny pipe-bowl, from which a thin glass tube conveys the ink to the paper. Each time the paper is moved on by pushing over the paper-shifting lever, and the circuit is thereby broken, the pen returns automatically to the inkpot on the "isobath" principle, as seen in Fig. 3.

A MODERN POLYPHASE CENTRAL STATION IN SWITZERLAND.

BY FRANK C. PERKINS.

The recent installation of polyphase apparatus at Zurich, Switzerland, is worthy of note. The great electrical manufacturing firm—The Maschinenfabrik Oerlikon, has its large establishment in the vicinity of that city and has installed a complete line of its apparatus in the Zurich Municipal Electric Supply Plant.

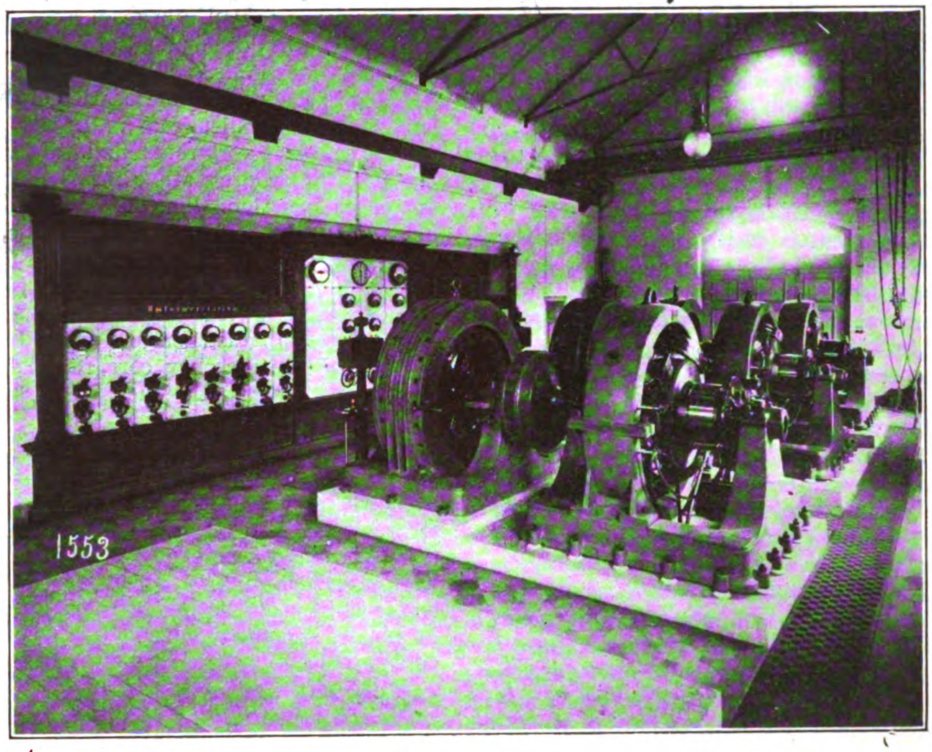

FIG. 2.—MOTOR GENERATOR SUB-STATION AT SELNAU, SWITZERLAND.

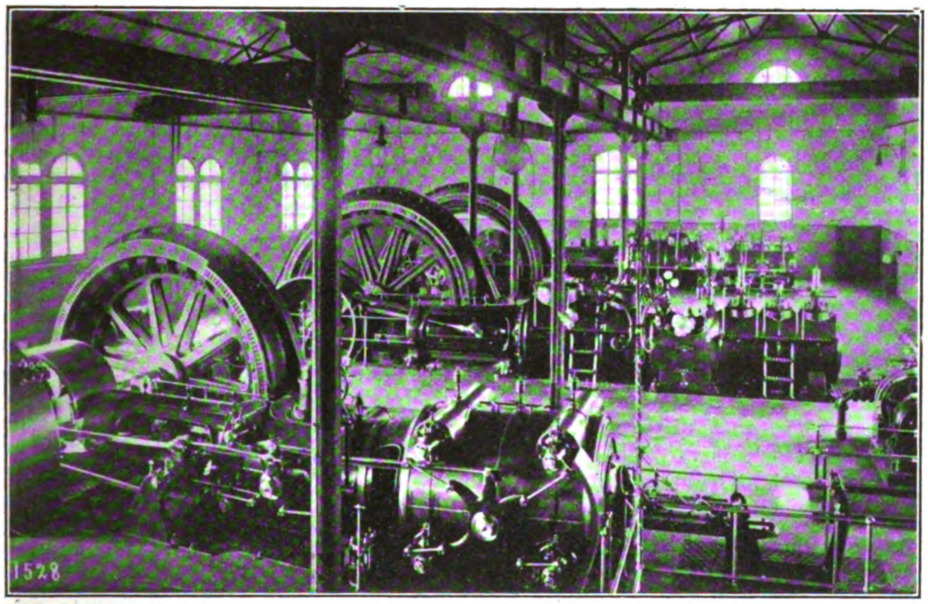

FIG. 1.—3,000 HP. POLYPHASE CENTRAL STATION AT ZURICH, SWITZERLAND.

The three direct connected units, seen in Fig. 1, consist of three polyphase generators, which are arranged so as to deliver either a Drehstrom or monophase current as desired. The unit in the immediate foreground has a capacity of 750 horse power and the two units in the background have each a capacity of 1,000 hp. The current is used for light, power and traction purposes, and is supplied from the generators at a potential of 2,000 volts.

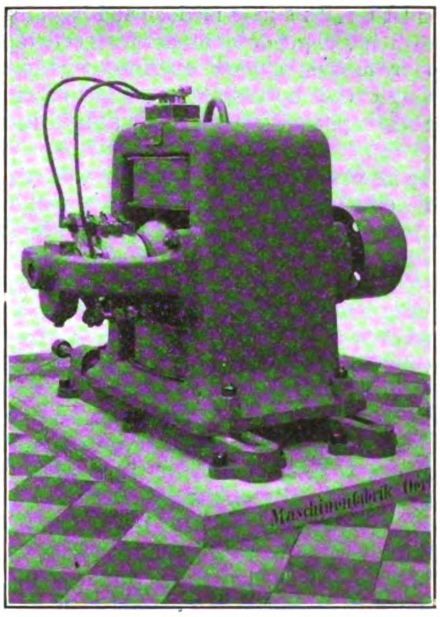

FIG. 3.—CONTINUOUS CURRENT MOTOR.

The illustration Fig. 2 shows the sub-sta-

Digitized by Google

tion at Selnau where the current is transformed to a direct current for use on the power and traction lines. There are in operation in this sub-station three Oerlikon motor generators. These combinations have each a capacity of 300 horse power, and consist of three phase motors operating directly at 1,950 volts, and at a frequency of 50 periods per second. The speed of the motors is 370 revolutions per minute. To each motor is connected a direct current generator by means of flexible couplings. Each generator supplies a continuous current of 200 kilowatts at a potential of 550 volts. The switchboard shown in the background in Fig. 2 is arranged to control the alternating polyphase current from the line at one end and the circuit breakers, switches and direct current measuring instruments are placed at the other end. It will be noted that a wooden framework is used with marble panels on which the various instruments are mounted.

The alternating motors used directly from the central station are of the three phase type built by the Oerlikon Company, while the direct current motors are of the type shown in Fig. 3. This station has been operated with great success, and while not of the largest in size, is in every way a modern installation.

THE PLANT OF THE ST. CROIX POWER COMPANY OF WISCONSIN.*

BY HENRY FLOY.

The considerable number of high tension long distance transmission plants already in successful operation might not render the completion and starting of a 25,000 volt plant of any particular interest, except that in all engineering work, and especially in electrical lines, the "newest" usually means something of a change from, and improvement upon anything previously constructed.

About two years ago the St. Paul Gas Light Company of St. Paul, Minn., owing to increasing business, the depreciation and antiquity of its generating apparatus and the expense of operating four distinct stations, foresaw that it must build a single modern and larger steam generating plant or arrange for securing current by means of long distance transmission through the development of one or more of the water powers within reasonable distance of St. Paul.

Upon investigation it was found that 27 miles east of St. Paul, on Apple River, in the State of Wisconsin, there was a natural fall of about 30 feet. Above the fall a dam could be built to a height of 47 feet thus affording with a slight drop in the river below the fall a total head of 82 feet. Apple River is fed from innumerable springs and some 25 lakes in North-Western Wisconsin and in consequence its discharge is remarkably uniform the year around. With the head afforded the minimum flow of water in the stream would yield about 2,000 hp. continuously and during most of the year nearly twice that amount. By the building of a dam, a large reservoir would be formed from which the impounded water could be drawn in any quantity necessary to carry the peak of any load in St. Paul, provided sufficient capacity was installed in water-wheels, generators and transmission line. It was thus demonstrated to the St. Paul Gas Light Company that the power that could be made available at Apple River Falls by a development of the character just outlined, would permit not only the complete shutting down of its four steam plants and avoid the necessity for building a modern steam plant but also provide it with nearly twice the salable output of its old stations.

Accordingly, about a year and a half ago, there was organized under the laws of the State of Wisconsin the St. Croix Power Company. This company is friendly to the St. Paul Gas Light Company and to the latter the former contracted to sell all the current it could generate by the development of a power plant at Apple River Falls.

Owing to the inaccessible location of the dam, being about five miles from a railroad station, and the country very rough and hilly, the importation of building stone for the dam was out of the question. The only material available at the falls is a brown sandstone, somewhat harder than the St. Peter rock underlying much of St. Paul and Minneapolis, but not hard enough to withstand constant attrition of the water. It was therefore decided to build the dam with a masonry core, resting on concrete foundations and enclosed in concrete facings.

The dam is of the arched type, being built as the arc of a circle having a radius of 450 feet. Near the north bank, close to the bed of the river, two steel pipes, each five feet in diameter are built into the concrete work and fitted with gates and crabs to permit control of the water while constructing the dam, or in time of repair, and the regulation of flow over the spillway in case of unusually high water.

At the south end of the dam are the trash racks and near them a sluice for conveniently disposing of the debris and ice.

The length of the spillway is 108 feet, and the total length of the dam 350 feet. There are 3,138 cubic yards of concrete and 5,025 cubic yards of rubble masonry in the dam.

It is a pleasure to state that although this dam has experienced extremes of temperature and stresses, it does not show any signs of cracks or leakage; and a number of engineers, experts on this class of work, who have seen the dam since its completion, unanimously agreed that the concrete work is of the highest grade and that the dam as a whole is a most perfect monolith.

In the dam at the head of the flume are three head gates and the iron trash rack, while at the lower end of the flume in the fore-bay are three tail gates with finer trash rack.

The penstock is 12 feet in diameter. It takes its beginning in the fore-bay and extends in a horizontal direction 88 feet to the brow of the hill, down which it continues 107 feet at an angle of about 45°. Then it turns again and continues in a horizontal direction 118 feet further. The penstock is of open hearth steel plate, ⅜ inch thick above the elevation 140.61 and seven-sixteenth inch below that elevation. The sheets of which the penstock is composed are held together by rivets, spaced two and one-half inches on centers, all rivet holes being punched one-sixteenth inch small and reamed out to full size; all joints being caulked and the whole painted with an iron preservative paint. The penstock is supported throughout its length on suitable masonry piers. On the hill-side, the earth has also been tamped under the pipe to give it additional support. The lower end of the penstock is provided with four branch pipes supplying four main sets of waterwheels, and a smaller fifth branch pipe ending in a "Y" supplies two separate exciter wheels. At the lower end the penstock is provided a gravity automatic relief valve having a discharge 12 inches in diameter. The last section of the penstock is provided with a blank opening for an additional and fifth unit in case it ever becomes desirable to install the same.

GENERATING STATION.

The generating station is a fire-proof structure of brick and iron, about 140 x 50 feet, divided longitudinally by a partition wall, thus separating the wheel-room from the dynamo-room.

In the wheel-room are four main sets of water-wheels, space being reserved for the fifth unit which may be added latter. Each set consists of two 36 inch special "Victor" wheels, mounted horizontally in a nine feet cylindrical steel wheel-chest from which they discharge through a six feet draft tube, eight feet long. Each pair of wheels is, of course, on a single shaft which extends through the end of the wheel-chest built into the partition wall, and is direct connected to a 750 kw. generator

Each wheel-chest is supplied from the penstock by its own feeder pipe in which is located a 56 inch gate valve operated from a shaft driven by a 7½ hp. electric motor. Each wheel-chest is surmounted by an automatic spring relief valve having an opening 12 inches in diameter. There are two exciter wheels, each direct connected to a 30 kw. direct current generator. The exciter wheels have their own branch feeder pipes, wheel-chests and separate gate-valves.

The waterwheel governors are of an improved type of the Geissler pattern. They are guaranteed to maintain the speed within 3 per cent. of normal for any instantaneous change in load not exceeding 25 per cent. of the load at the moment of variation. The governors are electrically controlled, being operated by the 125-volt excited current.

All the alternators are 750 kw., 3-phase, 800 volt, 60 cycle revolving armature, separately excited machines, running at 300 r.p.m. They will carry full load continuously without heating more than 40° C. above the temperature of the surrounding air, and have an inherent regulation slightly under 5 per cent. on non-inductive load.

The direct-current exciters are shunt wound, operating at 925 r.p.m., and each machine is of sufficient capacity to excite five 750 kw. alternators.

Across the lower end of the dynamo-room is the marble switchboard consisting of an exciter panel, four generator panels, two transformer panels, and a local service panel. The exciter panel is supplied with the usual instruments but the alternator panels are each equipped with one main oil switch, in series with two triple-pole, quick-break jaw switches, for throwing the machine on to either two sets of bus-bars. At the top of the panel is an ammeter, an indicating wattmeter, and a field ammeter with the usual synchronizing lamp, field-switch and voltmeter plug. The transformer panels will each be provided with an induction recording wattmeter, a single three-phase oil switch of special design, having a capacity of 1,500 kw. at 800 volts, and a potential indicator which enables operators at the generating station switchboard to determine the voltage at the St. Paul sub-station,

*Abstract of paper read at the 148th meeting of the American Institute of Electrical Engineers, New York, November 23, 1900.

Digitized by Google

regardless of the power factor of the load or the drop in the line.

The local service switchboard panel is equipped with switches for controlling the electric heaters by which the power-house is warmed, also the incandescent and arc lighting circuits and the motors driving the blowers.

There have been installed six air-blast transformers of 500 kw. capacity each, which step the voltage up directly from 800 to 25,000 volts. As operated, the transformers are connected in two sets of three each with "Y" connections. The low tension side of each set of transformers is joined directly with the transformer panel switches, and the high tension side with "spider" switches, through the use of which either bank of transformers may be connected to either or both of the transformer circuits.

TWENTY-FIVE THOUSAND VOLT OVERHEAD AND UNDERGROUND TRANSMISSION LINE.

Two three-wire, three-phase transmission circuits, each consisting of 24½ miles of overhead bare copper wires and three miles of underground cables connect the generating plant with the distributing station in St. Paul.

Both overhead circuits are carried on a single line of poles. The wires of each circuit are on one side of the poles and are supported so as to be at the verticles of an equilateral triangle, having 24 inch sides. The conductors are of No. 2 B. and S. medium hard-drawn copper wire, carried on glass insulators of the "Provo type"—the same as those used on the 40,000 volt transmission in Utah. The insulators are 7 inches in diameter and have a triple petticoat. They are mounted on special locust pins boiled in paraffin, carried on two 4 x 5 inch Oregon fir cross-arms. The poles are mainly of Oregon fir and are spaced not more than 110 feet apart. No poles less than 30 feet in length and eight inches in diameter at the top are used. Poles of minimum length are planted 5½ feet in the ground and six inches deeper for every additional five feet in their length. The line was designed to be practically level, irrespective of configurations in the earth's surface. The corners and angles in the line are reduced to as few as possible, consistent with securing a right of way at a reasonable price; no angle in a conductor at any insulator is less than 165°, thus avoiding any dangerous tendency to break the pins. In making a right angle turn special construction is used affording seven points of support for each wire. For slight turns two or three poles, as may be required, are set ten feet apart but no more than one insulator per wire is allowed on a single pole.

The transmission line really takes its beginning at the terminals of the step-up transformers in the dynamo-room of the generating station, whence it passes through the high-tension switches into a brick lightning arrester house abutting against the end of the power house. Here are located choke coils and lightning arresters. From the arrester house the wires pass out through circular openings in the wall, which are sheltered by a gabled roof, and run thence in a general western direction to a similar arrester house in the city of St. Paul, where they terminate in the heads of the underground cables.

There are two three-conductor lead-covered cables connecting the lightning arrester house with the distributing sub-station, located on Cedar street in the very center of the business section of St. Paul. These cables are in four-hole McRoy vitrified clay conduits laid in concrete. The conduits follow the grade of the streets except where it was necessary to pass under a number of railroad tracks in a deep cut. Here, the conduits end in the top of a brick well about fifty feet in depth, down which the cables drop, passing from the bottom of the well in other conduits to another well on the opposite side of the tracks, through which they rise again to the conduits laid below the pavements of the street.

In considering the use of cables for 25,000 volt transmission underground, the writer found that a number of reputable manufacturers not only declined to bid on his specifications, but would not entertain any proposition for furnishing such cables, even under their own specifications. There were only two companies that would undertake the work and accordingly a contract was entered into with these companies, one to furnish a rubber insulated and the other a paper insulated cable.

The specifications provided that the general design of both cables should be the same, that is, each conductor having an area not less than 66,000 cm., is composed of seven strands of copper wire, enclosed in insulation, the three laid up in jute and the whole enclosed in a jacket of the same insulating material as that used about each conductor. Outside of the jacket is the lead sheathing ⅛ inch in thickness, making the cable complete about 2¼ inches in diameter.

The "National" cable is insulated with paper treated with a secret compound. The insulation about each conductor is nine-thirty-seconds inch in thickness. That of the enveloping jacket, four-thirty-seconds inch thick. The covering of this cable is of lead protected on the exterior by a coating of tin.

The calculated resistance of each conductor between the generating and distributing stations is 23 ohms. The drop in voltage between the same points, for 3,000 kw., delivered with a 90 per cent. power factor, and 25,000 volts initial potential figures 7.7 per cent. operating both lines in multiple, which will be the usual practice.

SUB-STATION AND APPARATUS.

The distributing station in St. Paul is an iron and brick building designed to contain the necessary apparatus for reducing the potential and controlling and transforming the energy received over the transmission line, for distribution in the city of St. Paul. The building is 50 x 70 feet; two and a half stories in height. One-half of the building has a basement divided into two rooms, one, in which all the static step-down transformers and high tension switches are located, is connected by a tunnel with the street conduits; the other serves as a toilet room and place in which to locate the apparatus for heating the station.

Each conductor of two high-tension cables passing through the tunnel into the transformer room, ends in one terminal of a single-pole knife switch, to be operated only when current is off the line and installed to permit convenient testing of cables, etc. The other terminal of each switch is connected to a high-tension bus-bar, from which taps are taken off to the high-tension switches controlling the circuits to the different sets of transformers. The ends of the cables are also connected to static discharges, which are merely a number of standard lightning arresters, connected in series.

The high-tension bus-bars and their taps to the high-tension switches and from the switches to the transformers, are single conductors insulated with one-fourth inch of best Para compound, and guaranteed to withstand 25,000 volts continuously. The conductors are carried in conduits made of wood pulp indurated with asphaltum, manufactured by the Fibre Conduit Company. The conduits are guaranteed to withstand 20,000 volts without breaking down.

The high-tension oil switches are of the single-pole three-break type, operating under oil and designed to break 25,000 volts and 50 amperes. The switches are closed by hand but opened by the releasing of a latch controlled by a local circuit from the main switchboard up-stairs. There are 24 high-tension switches in all—12 connected with each set of the cable bus-bars. As all high-tension work is three-phase, this necessitates the closing of three switches to connect any set of transformers with either set of bus-bars.

There are four banks of static step-down transformers—two banks consisting of three 22,500 to 78-volt oil-cooled 300 kw. three-phase to six-phase transformers and two banks of two 22,500 to 2,100-2,700-volt oil-cooled 200 kw. three-phase to two-phase transformers.

Each one of the 300 kw. transformers has a single winding on the primary, and two entirely distinct and separate windings on the secondary. By connecting three of these transformers in a set, the three-phase to six-phase transformation is effected. One set of these transformers supplies current to the rotary converters, operating between the positive and neutral wires, and the other set to those rotaries operating between the neutral and negative wires of the Edison three-wire system of distribution throughout the city. There is kept on hand a spare transformer in case of break-down, but as all transformers in the sub-station are connected in delta, it is perfectly feasible to successfully operate although there are but two transformers of a set connected in circuit. In fact, this was the method of operating for the first few weeks after starting the plant and until the remainder of the transformers were received.

The two identical sets of three-phase to two-phase 200 kw. transformers provide for the alternating current distribution throughout the city. On the front of each transformer case is mounted a quick-break multipoint switch connected with leads brought out from the secondary windings of the transformers. The movement of the switch throws more or less turns of the secondary in circuit and thus adjusts the potential in steps of 21 volts to any desired point between 2,100 and 2,700 volts.

The use of six-phase transformers and converters is novel. The reason for the adoption of six-phases instead of three-phases was to secure the advantages of reduction of copper losses in the armature, and the accompanying reduction of temperature and its better distribution. At first sight it might seem that the increased complexity involved in the use of six-phases would not counterbalance the advantages to be gained. Practically, however, the use of six rings and the necessary additional taps to the windings on the armatures amount to nothing in the operation of the machines. The dividing of the secondary windings on the transformers for two independent circuits results in no complication or expense. On account of the large current, the use of six conductors between the transformers and switchboard and between the switchboard and rotaries was necessary whether three-phase or

Digitized by Google

six-phase machines were installed. The switchboard is practically the same for either number of phases except that the number of main switches was increased from two to three. This disadvantage, however, may be disregarded when a decided increase in the capacity of the rotaries is secured. The rotaries are ordinarily started from the direct-current end, but are equipped with break-down field-switches and designed for starting from the alternating-current end when necessary.

A Medal for the Farr Telephone Exhibit.

Mr. Drake, the Director of Machinery and Electricity at the Paris Exposition, has informed the Farr Telephone & Construction Supply Company, 357 Dearborn street, Chicago, that it has been awarded a bronze medal by the International Jury of Award for the Paris Exposition.

American Motors for European Canals

F. W. Hawley, who has been commissioned by large American interests to advocate and explain the principle of electric propulsion for canals, has returned to London from the Continent after a successful journey. He reports that plans for electric canal service have been adopted in Belgium and Holland, and that the waterways of those countries will be equipped with motors similar to those proposed for operation on the Erie Canal. These motors will be provided by an American company, and the entire system of electric propulsion of canal boats will be introduced from the United States. Mr. Hawley has been working with excellent results in France, and asserts that a bill has been prepared for submission to the Legislative Chambers for the introduction of the same system of canals in that country. He also expects that electric motors for French canals will be ordered from the United States.

The National Telephone Company.

The National Telephone Company, 33 and 35 Lafayette avenue, Detroit, Mich., is manufacturing a line of high-grade telephone instruments for which there is much demand. This concern—which is an independent one—handles the central energy pole system, the central energy tower system and the central energy underground system. The company has branch offices at Vandalia, Ill., Chicago, St. Louis and Milwaukee, as well as in Paris, Berlin and London. The president of the company is Mr. Phil Geluk, while the secretary and manager is Mr. W. J. Kurtz, M. E.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended November 30:

Amsterdam, 1 case, $200; Antwerp, 25 packages, $1,728; 1 case $127; Argentine Republic, 49 cases, $3,605; Brazil, 82 cases, $4,244; Bremen, 14 packages, $842; British West Indies, 11 cases, $140; British Possessions in Africa, 25 cases, $884; Central America, 40 packages, $773; Christiania, 2 cases, $25; Chili, 25 cases, $505; Cuba, 84 packages, $12,354; Dresden, 2 cases, $75; Dutch West Indies, 17 packages, $502; Ecuador, 10 packages, $186; Genoa, 214 packages, $47,872; Glasgow, 11 cases, $2,365; Hamburg, 7 cases, $3,255; 20 packages, $1,850; Havre, 38 packages, $3,107; Hayti, 2 cases, $45; Hong Kong, 189 cases, $6,633; Japan, 71 cases, $22,707; Leeds, 2 cases, $60; Liverpool, 138 packages, $17,989; 2 packages motor trucks, $175; 62 electric cables, $25,075; London, 188 packages, $14,972; Manchester, 6 packages, $690; Marseilles, 20 cases $1,860; Mexico, 112 packages, $11,351; 5 cases $187; Milan, 41 cases, $5,127; Naples, 40 packages, $560; Newcastle, 51 cases, $7,830; New Zealand, 1 case, $71; Oporto, 1 package, $70; Peru, 2 cases, $33; 50 packages, $1,390; Porto Rico, 57 packages, $1,604; Revel, 48 cases, $516; Riga, 17 packages, $3,403; Southampton, 80 cases, $5,147; 27 packages, $1,517; St. Petersburg, 2 cases, $2,206; U. S. Colombia, 50 packages, $1,230; Vienna, 11 cases, $1,608.

PERSONAL MENTION.

Mr. H. Durant Cheever is in London for a long visit, looking after the large foreign business of the Okonite Company of New York.

Mr. Horatio A. Foster has established headquarters as a consulting electrical engineer at 310 Chestnut street, Philadelphia, Pa.

Mr. Herman Wilkiemeyer, vice-president and general manager of the Evansville (Ind.) Gas & Electric Company, died recently of Bright's disease at Cincinnati. His friends claim he was the inventor of the Welsbach light.

INCORPORATIONS.

The Enberg Electric & Mechanical Works, St. Joseph, Mich. Capital stock, $5,000.

The Mayfield Electric Light, Heat & Power Company, Mayfield, Pa. Capital stock, $5,000.

The Story City Electric Light & Power Company, Story City, Ia. Capital stock, $10,000. J. Molstre president.

The Bliss Electric Car Lighting Company, Newark, N. J. Capital stock, $250,000. Incorporators: William L. Bliss, John L. Bliss and Henry Sanger Snow.

The Consolidated Safety Third Rail Electric Company, New York City. Capital stock, $100,000. This company expects to secure control of all third rail plants.

The Electric Equipment Company, New York City. Capital stock, $5,000. Directors: C. J. Klein and C. L. Sefort, New York City, and H. E. Wadsworth, Brooklyn.

The Des Moines Edison Light Company, Des Moines, Ia.—to do an electric light business. Capital stock, $1,125,000. Incorporators: H. C. Levis and H. M. Francis, both of New York.

The New Jersey Light, Heat & Power Company, Camden, N. J.—to furnish electric light, heat & power. Capital stock, $200,000. Incorporators: H. O. Burt, H. J. Smith, J. B. Miller, H. C. Stewart and W. B. Freland.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 27, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

662,386. Electric Traction for Tramway or Similar Vehicles. Arthur Baisieux, Brussels, Belgium. Filed July 31, 1900.

662,419-662,420. Electric Railway. William Grunow, Jr., Bridgeport, Conn., assignor to the McElroy-Grunow Electric Railway System, same place. Filed April 5, 1900.

662,423. Current-Collector. William Grunow, Jr., Bridgeport, Conn., assignor to the McElroy-Grunow Electric Railway System, same place. Original application filed April 5, 1900. Divided and this application filed May 21, 1900.

662,456. Safety Device for Street-Railway Cars. Thomas Mulholland, Pittsburg, Pa. Filed Aug. 28, 1899.

662,497-662,498. Railway-Crossing Signal. Nicholas Ratchford, Greenville, O. Filed June 20, 1899, June 26, 1899.

662,595. Trolley-Wire Suspension. John W. Haynes, Manchester, Conn. Filed March 10, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

662,510. Incandescent-Lamp Socket. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 20, 1899.

662,580. Apparatus for Electrically Lighting Railway-Carriages, etc. Charles Vicarino, Nancy, France. Filed April 24, 1900.

662,727. Attachment for Arc-Lamps. Edwin B. Jones, Chatham, Can. Filed May 26, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

662,450. Controller for Electric Motors. John B. Linn and Maxwell W. Day, Schenectady, N. Y., assignors to the General Electric Company of New York. Filed Sept. 17, 1898.

662,465. Commutator. Edward D. Priest and George L. Schemerhorn, Schenectady, N. Y., assignors to the General Electric Company of New York. Filed June 30, 1900.

662,480. Automatic Circuit-Controller. George H. Whittingham, Baltimore, Md. Filed March 19, 1900.

662,570. Ceiling-Switch. Ernest A. Lowe, North Plainfield, N. J., assignor of one-half to Charles W. Leveridge, Plainfield, N. J. Filed June 4, 1900.

662,630. Brush-Holder for Electric Machines. Sidney H. Short, Cleveland, O., assignor, by mesne assignments, to the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa. Filed July 28, 1898.

662,758. Commutator-Brush Holder. Harry Bishop, New York City. Filed July 3, 1900.

662,772. Electric Motor. Joseph Darling, Chicora, Pa. Filed Sept. 1, 1900.

662,784. Apparatus for Interrupting Relatively High Potential Circuits. William Grunow, Jr., Bridgeport, Conn., assignor to the McElroy-Grunow Electric Railway System, same place. Filed Nov. 20, 1899.

662,785. Apparatus for Rupturing High-Potential Electrical Circuits Without Dangerous Arcing. William Grunow, Jr., Bridgeport, Conn., assignor to the McElroy-Grunow Electric Railway System, same place. Filed June 13, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

662,543. Telephone-Switch. Levi M. Neher, North Manchester, Ind. Filed April 4, 1900.

MISCELLANEOUS.

662,409. Apparatus for Separating Gold from Magnetic Sands. Elmer Gates, Chevy Chase, Md., assignor to Theodore J. Mayer, Washington, D. C. Filed March 19, 1900.

662,410. Magnetic Separation. Elmer Gates, Chevy Chase, Md., assignor to Theodore J. Mayer, Washington, D. C. Original application filed March 19, 1900. Divided and this application filed April 14, 1900.

662,411-662,412-662,413-662,414. Magnetic Separator. Elmer Gates, Chevy Chase, Md., assignor to Theodore J. Mayer, Washington, D. C. Filed April 14, 1900, July 12, 1900.

662,422. Electrical Resistance. William Grunow, Jr., Bridgeport, Conn., assignor to the McElroy-Grunow Electric Railway System, same place. Filed April 5, 1900.

664,444. Insulating Composition. Carl Jung, Vienna, Austria-Hungary, assignor of two-thirds to Adolf Kittel and Adolf Brecher, same place. Filed Dec. 19, 1899.

662,463. Casing for Electrical-Conductor Joints. George H. Paul, New York City. Filed June 2, 1900.

662,466. Lightning-Arrester for Safety Cut-Outs for Electric Circuits. Joseph Sachs, Hartford, Conn. Filed Sept. 28, 1899.

652,484. Electric Top for Gyroscopes. Emil Ziehl, Berlin, Germany. Filed Dec. 26, 1899.

662,491. Portable Electrical Device. John S. Mead, Buffalo, N. Y., assignor of one-half to William Comerford, same place. Filed Jan. 30, 1900. Renewed Oct. 24, 1900.

662,501. Safety Cut-Out for Electric Circuits. Joseph Sachs, Hartford, Conn. Filed Sept. 28, 1899.

662,527. Telegraph Signaling Apparatus. Edward B. Ellicott, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 8, 1899.

662,537. Electric Smelting Furnace. Hugo Koller, Nuremberg, Germany. Filed May 17, 1900.

662,549. Semaphore-Operating Mechanism. Judson Shoecraft, Eskridge, Kans., assignor to Charles C. Gardiner, Bradford, Kans. Filed June 23, 1900.

662,587. Insulated Support for Electric Conductors. Charles C. Blake, Portsmouth, N. H. Filed May 18, 1900.

662,622. Electric Battery. Arthur W. Harrison, Los Angeles, Cal., assignor of one-half to William A. Fruhling, same place. Filed June 16, 1900.

662,657. Electric Burglar-Alarm. Henry Rohrdantz, Buffalo, N. Y. Filed April 14, 1900.

662,679. Reversible Primary Battery. Leon W. Pullen, Camden, N. J., assignor to the Pullen Battery & Electrical Manufacturing Company of New Jersey. Filed Sept. 16, 1899.

662,707. Electrical Connector. Henry Blackman, New York City. Filed June 6, 1899.

662,719. Electric Fire-Alarm. Charles L. Haight, Poughkeepsie, N. Y. Filed Jan. 25, 1900.

662,752. Transmission of Electrical Impulses. Frederick Bedell, Ithaca, N. Y. Filed July 6, 1899.

662,803. Burglar-Alarm. Junius L. Murphy, Denver, Col. Filed Feb. 4, 1899.

662,833. Railway Signaling. Samuel D. Strohm, Philadelphia, Pa., assignor to the Strohm Automatic Electric Safety Block Signal Company, same place. Filed Aug. 29, 1891. Renewed June 5, 1900.

THE TELEPHONE WORLD.

The Independent Company Making Great Progress.

The New York "Commercial" says that the removal of the main offices of the Erie Telephone Company to New York calls attention to the work which is now being carried on by the officials and management of the Telephone, Telegraph & Cable Company of America.

For the past few months they have been engaged in the work of centralizing the executive departments of the numerous companies absorbed and in harmonizing and connecting the companies which have hitherto been operated independently.

For nearly a year after the big national opponent of the American Bell Company was organized the work of the promoters of the company was confined mainly to acquiring independent companies. While the company has not as yet given up the purchasing of small companies, which will provide links in the general national system, its best efforts were directed to organizing the companies it has acquired.

W. H. Beers, a director of the Telephone, Telegraph & Cable Company of America, who was formerly located in this city, is now in the West. He has taken up headquarters at Fort Wayne, Ind., which is the district where the work of organization is now being centralized. In Indiana, Ohio and other Western States the independent telephone movement has had its greatest success, and it is in this district where the greatest work is now being done.

A large number of companies in actual operation have been absorbed by the National Company in Ohio, Indiana, as well as Michigan. These companies are now being made links in the great national telephone system which is being built up in opposition to the Bell.

So far the new International Telephone, Telegraph & Cable Company, which was formed this summer, has not taken over the Telephone, Telegraph & Cable Company of America, as it was believed it would after it was formed. The same interests which control the newly formed company also control the old company, so that the work begun by the latter will go on under any circumstances.

There is great interest in the coming decision by Judge Brown in the cases of the Bell Telephone Company against the National and Century Telephone. There have been times in the past, says a Boston, Mass., paper, when a decision in a telephone case has seriously affected the stock market, in one instance the fluctuations varying over 100 points, but there is no probability that there will be any such result in the present instance, although the decision is a most important one inasmuch as it will determine the validity of the Berliner patent. No one but Judge Brown knows the nature of the decision, or when it will be given. There are intimations that whatever the decision may be, the case will be carried to the Court of Appeals, and from there to the United States Supreme Court. Another telephone case, that of the Western Union against the Bell, a suit growing out of contracts between the two corporations, was argued before Judge Colt some time ago and now awaits decision.

The directors of the Dubuque Telephone Company held a meeting a short time ago and heard the reports of the officers. These showed the company to be in a most prosperous condition under the management of President Stevens, also that the company has a bright future before it. It was decided to declare a dividend of 20 per cent.—something that the company has been doing since it was organized. About fifteen new telephones per day are being put in through the underground conduits. The list now includes several hundred subscribers in Dubuque, Ia.

One of the most important moves that has been made in independent telephone circles is the deal between the United States Telephone Company and the Pittsburg & Allegheny Telephone Company. By the terms of the contract the United States Company gains control of long distance lines, which will make complete the connection between Cleveland and Pittsburg and ultimately reach to Baltimore.

The corporation owning several independent telephone exchanges in Texas has a representative in Austin who will shortly apply to the city council for a franchise to put in a system. A franchise was refused some months ago by a vote of 4 to 3, but there has been a change in the council.

The Island Telephone Company was recently chartered to connect Charleston, James Island, Wadmalaw, Edisto Island and John's Island, S. C. The capital stock is $4,000, and the officers: Reginald F. Fennell, president; Cecil G. Fennell, vice-president, and Malcom O. Duncan, secretary.

Bath, Me., is to have 100 new telephones this month.

Northern Pacific Railroad to Use Telephones.

According to a recent report from St. Paul, Minn., the Northern Pacific Railway has decided to substitute the telephone for the present telegraph system of the road and will build and equip long-distance and divisional telephone lines to take the place of the telegraph, wherever it shall be deemed practicable. The officials of the road believe that most of the telegraphing that is now done in connection with the traffic department can be as well or better performed by telephone.

The plan is to place each station in a division in direct communication with the division headquarters, and the various division headquarters are to be connected with the general offices by long distance lines.

In this way much information of importance to the traffic and operating departments which, on account of the limitations of the telegraph system, must now be sent by mail, can in the future be telephoned. Telephones are now used quite extensively and with marked success on some Eastern roads. The Northern Pacific, however, will be the first of the Western lines to adopt this system.

A meeting of the Southern Illinois Telephone Association, which embraces all the independent companies of Southern Illinois, was held recently in Benton, Ill., in connection with a representative of the Kinloch Company of St. Louis, with a view of arranging long distance connection from Southern Illinois points to St. Louis and other distant points. A proposition was submitted to the Kinloch people by the association, and if it is accepted, which it likely will be, connection will be made.

There is a movement on foot to have a telephone line built from Vernon to Knoxboro, N. Y., and also from Vernon to Kenwood, N. Y. Whatever is done in regard to these two lines will have to be done by local enterprise. The expense will not be very heavy. The lines will be run into the office of the Rome Home Telephone Company, so that parties having 'phones in their home can also talk with Oneida, Verona, Lowell, Rome and many other places into which the lines of the company run. It is probable a meeting will be held soon to consider the matter.

A news telephone service has been established at Budapest, the object of the scheme being to supply subscribers with reports of all the important occurrences which are ordinarily chronicled in the daily papers. The service has a main line 168 miles in length, and it is connected with private houses and various public resorts. Between 7:30 A.M. and 9:30 P.M. 28 editions of news are spoken into the transmitter by ten leather-lunged individuals who work in shifts of two.

The Rochester Telephone Company, at Honeoye Falls, N. Y., which has been delayed for several weeks, has succeeded in making its connection with the Mendon Center Telephone Company's line. The exchange and toll station are now opened for the public's use.

A farmers' telephone line is being constructed from Rushford to Choice, via Bratsberg, Minn. Connections will be made with the Phoenix exchange, thus giving the farmers all the advantages enjoyed by the toll lines.

The Citizens' Telephone Company has completed a metallic service line from Jackson to Horton and Hanover, Mich., and next spring the line will be continued to Moscow, Hillsdale and other neighboring towns in that State.

The Pacific States Telephone Company has an inspector looking over the route between North Yakima and Prosser, Wash., with a view towards establishing a long distance service at the latter place.

At Mangum, Okla., Mr. Brittain from Texas is looking over the situation with a view of putting in a telephone exchange, and also running a line to Granite, Combs and Cordell, Okla.

The Long Distance Telephone Company of Virginia is now constructing a telephone line from Forest to Lychburg, Va. This will, when completed, give two lines for communicating by 'phone from Forest to Virginia cities.

The Citizens' Telephone & Construction Company of Nashville, Tenn., has been chartered, with a capital stock of $10,000.

The Cincinnati, O., Telephone Association has made the offer to the board of education to place a telephone in every public school building free of charge.

Municipal 'Phone Service for Toronto.

The city of Toronto, Ont., lately started on the first stage of its municipal telephone project. It has issued contracts which citizens are to sign and return to the city clerk, and as soon as 3,000 citizens have offered to become subscribers then a by-law will be submitted to raise the necessary money and the system will be put into operation.

There is a movement on foot to effect a combination of the Virginia Long Distance Telephone Company with the Interstate Telephone Company of North Carolina. The Virginia Company is gradually connecting the various local lines so that when it is completed the combination referred to may be effected. This matter is not new, but at a meeting some time ago of the Virginia Company the subject was discussed, and it is not unlikely that the result will be satisfactory to both companies when the local companies become united.

From Tahlequah, I. T., comes the report that the Cherokee Legislature has passed a few bills granting franchises to build telephone lines in the Cherokee Nation, one line to be put in from Owasso to Caney, Kan., one line from Stillwell, I. T., by Tahlequah to Wagoner, and a line from Vinita along the St. Louis and San Francisco Railroad to Red Fork, I. T.

The Dunkirk, N. Y., Home Telephone Company, organized two months ago, and which holds a franchise granted by the common council, will commence work on its new line this week. All equipment has been shipped there, and the poles and wire will be laid and strung in about two weeks.

Work has begun on a new telephone system at Sanford, N. C. The holes are being sunk for the posts. It is proposed by Mr. Will Wynn, who will build the system to connect Raleigh, Greensboro and Richmond, Va., with Sanford. He has lately been making the necessary arrangements for the same.

A long distance telephone will be constructed between Alexander City and Dadeville, and thence to Opelika, Ala. From the last named place the line will be continued to Birmingham in that State.

The Belmont Telephone Company has commenced to place its wires in Bridgeport, W. Va., and it is understood will soon begin to set poles in other places where it has secured franchises.

The Diamond State Telephone Company, which has its main office in Dover, Del., has completed its line through Easton.

The Warren, Minn., Telephone Company's building was entirely destroyed by fire a short time ago.

The Dakota Telephone Company is improving its service in Huron, S. D.

TELEPHONE INCORPORATIONS.

The Cass County Telephone Company, Harrisonville, Mo.—to operate telephone lines. Capital stock, $2,000. Incorporators: W. B. Scruggs, H. B. Moody, Mary Moody, T. W. Clement, Dora B. Scruggs.

The Juniata & Susquehanna Telephone Company, Harrisburg, Pa.—to operate lines in Northumberland, Dauphin, Cumberland, Franklin, Perry, Snyder, Juniata, Mifflin, Huntingdon and Fulton Counties. Capital stock, $1,000.

The Ada Telephone Company, Ada, Minn.—to operate telephone lines. Capital stock, $1,000. Incorporators: W. H Matthews, R. S. Matthews, both of Ada; D. C. Jones, of Gary; D. E. Fulton, of Beltrami; S. M. Calkins, of Twin Valley.

The El Dorado Springs Telephone Company, Kansas City Mo. Capital stock, $10,000. Incorporators: C. A. Ross, A. P. Nichols, H. Brumback, K. Jenney, all of Kansas City; F. W. Hiatt, of El Dorado Springs.

The Quick Telephone Company, Harrisonville, Mo. Capital stock, $20,000. Incorporators: Shem Zook, Isaac Zook, East Lynne; Maurice Quick, Quick City; P. H. Wirt, Harrisonville, and others.

The Harrison Telephone Company of Harrison, O. Capital stock, $5,000. Incorporators: John L. Wallefeld, Alexis F. Burk, Robert P. Burk, John C. Bevis and Francis Nolowell.

The American Messenger 'Phone Call Company, Wilmington, Del. Capital stock, $100,000. Incorporators: E. Everitt, W. S. Kolb, G. Le Maistre, all of Philadelphia, Pa.; G. W. Kimball, of Wilmington.

GENERAL ELECTRICAL NEWS.

Lighting.

Amboy, Minn.—The citizens of this place are agitating the question of building an electric light plant.

Baton Rouge, La.—R. A. Hart of this city wants prices on a small electric light plant.

Barberton, O.—The city council will advertise for bids for lighting the city by electricity.

Blue Rapids, Kan.—A. E. Winter, secretary of the Commercial Club, is investigating the cost, etc., of putting in an electric light and power plant here.

Burlington, Ia.—Mayor Marquardt and others are investigating the cost, etc., of installing an electric light plant in this city.

Chattanooga, Tenn.—The Consigners' Favorite Box Company of this city is in the market for an electric light plant. Address Box 239, Chattanooga.

Chicago, Ill.—City Electrician Ellicott will ask that $970,000 be appropriated in 1901 for more street lights.

Clear Lake, Minn.—Mr. Mortenson, the owner of the electric light plant at Toronto, has been looking over the field with a view of putting in a plant here.

Cuba, Ill.—This town is preparing to build an electric light plant.

Fredericksburg, Va.—This city has sold $12,000 in bonds for the purpose of building a new electric light plant.

Hickory, N. C.—E. L. Shuford Manufacturing Company of this city invites bids on lighting apparatus for a cotton mill.

Jacksboro, Tex.—The Jacksboro Light & Power Company has reorganized with J. Hessley, president. The company will improve its plant.

Jacksonville, Fla.—The American Kaolin Company, six miles south of here, is preparing to install an electric light plant in its works.

Jerseyville, Ill.—It is reported that a local company has been formed here to establish a new electric light plant. The plant now in operation is owned by St. Louis parties.

Kissimmee, Fla.—W. C. Maynard has submitted a proposition to the city council to install a modern electric light plant.

Larned, Kan.—The electric light plant of this city was purchased by Mr. Henderson. Improvements and repairs will be made by the new purchaser.

Little Falls, N. Y.—I. W. Lovenheim has asked permission to erect an electric light plant here.

Marshfield, Vt.—M. E. Beckley and M. C. Ide have under consideration the putting in of an electric light plant in the Ide factory.

Mayville, Mich.—This town wants electric lights and will give a bonus to any reliable person who will put in a good plant.

Mexia, Tex.—W. S. Gibbs, of Huntsville, Tex., is investigating with a view of establishing an electric light plant here.

Milwaukee, Wis.—The Milwaukee Electric Company is looking for a site and planning to erect a $40,000 plant next summer.

Richmond, Ind.—Consulting Engineer J. B. Nelson, of Indianapolis, has handed in his completed plans and specifications to the council committee on the electric light plant. The establishment and equipment of the plant will cost $150,000 and will be erected at once.

Ripon, Wis.—Bids for 5, 10 or 15 years will be received until January 3 for a franchise to supply electric light for this city. Address F. W. Allen, city clerk.

Rochester, N. Y.—A recent fire wrecked the Citizens' Electric Light & Power Company's plant, entailing a heavy loss.

Sea Isle City, N. J.—A new addition will be erected to the electric lighting plant here under the direction of T. E. Ludlam.

Sparta, Tenn.—The Sparta Telephone Company is considering the erection of an electric light plant here.

South Boston, Va.—The South Boston Electric Light & Power Company with $200,000 capital stock has been chartered by R. W. Lawson, J. J. Lawson and R. S. Barbour, to maintain and operate an electric light plant.

Tillamook, Ore.—This city is to have a new electric light plant. The present plant, which has been running for several years, has outlived its usefulness, and is closed down.

Waynesville, N. C.—This city has decided upon the establishment of a plant for electric lighting. F. W. Miller, city treasurer.

Welland, Ont.—The Welland electric light plant was completely destroyed by fire a short time ago.

Wenona, Ill.—Messrs. Robinson & Fosbender of the Wenona Light & Power Company have gained control of the franchise of the Spring Valley Electric Light Company. The new purchasers will at once make several thousand dollars' worth of repairs on their newly acquired property.

Street Railways.

Barnesville, O.—It is stated that a movement is on foot to construct an electric railroad from Woodsfield to this place.

Beaumont, Tex.—The city council has granted to J. H. Kirby and others a franchise over the streets of this city for an electric street railway system.

Bloomsburg, Pa.—The construction of the Columbia-Montour Electric Railroad in the near future is now an assured fact.

Caldwell, O.—A project for building an electric railroad between here and Beverly is said to be under consideration by some New York capitalists.

Des Moines, Ia.—It is announced here that a syndicate has been formed for the purpose of building an electric or compressed-air railway out of this city to connect with the Iowa Central Railway at Newton.

Erie, Pa.—The Terminal Street Railway Company of this city was recently incorporated to build a trolley line here. The capital stock is $7,500 and C. S. Strong is its president.

Fabius, N. Y.—The Delaware, Lackawanna & Western Railroad is surveying for an electric road from Apulia to this place through to Cuyler.

Hereford, Pa.—A new electric railroad, which will connect with the road constructed from Reading to Boyertown at the latter place, and with the Lehigh Traction Company's line at Emaus will be built in the spring.

Kansas City, Mo.—The fourth cable line has been converted into an electric line in this city during the last two years. There are six cable routes left. Electricity will be substituted on at least two of these lines within the next eighteen months, and the officials are looking forward to the time when they will sell the last cable to the scrap-iron dealer.

Lima, O.—The Lima & Findlay Electric Railway Company of this city was recently incorporated with $20,000 capital stock.

Marietta, O.—A company composed of Eastern capitalists has been organized to build an electric road from this city to Lowell, a point 20 miles up the Muskingum River.

Marshall, Tex.—The city council lately granted to A. R. Wheeler & Co. of St. Louis a 50-year franchise to build an electric street railway and operate the same over streets in this city.

Niles, Mich.—J. W. Van Cleave of New York City, promoter of the Interstate Railway Company, has applied to the council for a franchise to run an electric line through this city. The terminus will be at St. Joseph and the line will run from South Bend, Ind., through Niles, Buchanan, Berrien Springs and Benton Harbor.

Parkersburg, W. Va.—The Baltimore & Ohio Railroad branch between here and Marietta will be converted into an electric line.

South Glens Falls, N. Y.—Hon. Warner Miller, Hon. Warren Curtis and a number of others who own a franchise permitting the construction of a road from here to Palmer, Saratoga County, have had a survey made and are anxious to have the road built.

St. Augustine, Fla.—Atlanta parties have become interested in a plan to build an electric railway in the suburbs of the city and are in correspondence with Mayor Boyce.

West Chester, Pa.—An electric railway from here to Oxford is among the probabilities for next year.

Youngstown, O.—The capital stock of the Youngstown & Sharon Electric Railway Company has been increased from $200,000 to $600,000.

Manufacturing.

Detroit, Mich.—Frederick and Edward Leadbeater and John G. Hacking have incorporated as the Low Water Electric Alarm Company, and will manufacture the Leadbeater electric apparatus for use on steam boilers. The capital stock is $25,000.

Kittery, Me.—President Dallas W. Cobb and treasurer John E. Fuller of Mansfield, Mass., are the officers of a concern recently organized here known as the H. A. Fisher Manufacturing Company, which will manufacture and deal in electrical goods with $10,000 capital stock.

Los Angeles, Cal.—A lately organized concern, known as the Pacific Electrical Works, has purchased land here where a large and completely equipped factory for electrical work, insulation of electric wires, etc., will be in operation by the middle of January next. The company will start operations with a capital of $250,000.

Topeka, Kan.—The Overton Manufacturing Company of this city has been awarded the construction of the new electric light plant here.

Company Matters.

Buffalo, N. Y.—The Franklinville Electric Company has been reorganized and the new company will soon have the plant in operation again.

Jersey City, N. J.—The stockholders of the Cahill Writing Machine Manufacturing Company held their annual meeting at the office of the company in this city recently. They voted to change the name of the company to the Cahill Electric Typewriter Company, and to amend the charter to permit the capital stock to be increased from $710,000 to $1,250,000.

Plano, Ill.—The Plano Electric Light & Power Company has changed its name to the Plano Light & Power Company, and increased its capital stock from $8,000 to $15,000.

Power and Transmission.

Berrien Springs, Mich.—Chas. A. Chapin is about to spend $100,000 in the construction of a dam at Berrien Springs, for the purpose of supplying the South Bend Street Railway Company with power.

San Francisco, Cal.—The Beckwith Power Company has been formed lately with Don Ray, S. C. Denson, William M. Pierson, Charles Ray and Byron D. Beckwith as directors, with a capital stock of $750,000. This company will operate electrical plants and build railways in the Sacramento Valley.

Schenectady, N. Y.—It has been definitely decided that manufacturing concerns of this city will utilize all the power the Niskayuna Power Company will be able to generate at its plant now in process of construction.

Weymouth, N. J.—A syndicate consisting of Philadelphia and New York capitalists has purchased a site along the Egg Harbor River at this place for the purpose of erecting an electric power house to supply Atlantic County with electricity.

Automobiles.

Chester, Pa.—John Welsh, an employe of Messrs. Jenkins & Burk, carriage builders, has constructed a home-made automobile. While the machine is, as Mr. Welsh admits, crude, there is said to be merit in its construction.

Knightstown, Ind.—The Knightstown Buggy Company of this city has filed articles of incorporation with the Secretary of State, with a capital stock of $30,000. Robert Silver, Mason Waller and Robert Logan are the directors. The company will manufacture automobiles in the near future.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c. casting, 16⅝@16¾c.

The owners of the Knoxville, Tenn., Traction Company purpose to spend $2,000,000 in a local street railway, electric light plant and coke plant.

The Chicago City Railway Company has declared a dividend of 3 per cent., payable December 31. Books close December 15 and reopen December 21.

At the annual meeting of the stockholders of the Metropolitan Street Railway Company held in New York on Monday the present directors were re-elected.

The directors of the Telegraph, Telephone and Cable Company have passed a resolution assessing the capital stock 10 per cent., or $5 per share, payable December 31.

Holders of temporary certificates for the stock of the Consolidated Railway Lighting and Equipment Company may receive their stock on presentation of the certificates to the Morton Trust Company, New York City.

At the annual meeting last week of the West End Street Railway Company of Boston, Samuel Little was succeeded on the board of directors by C. M. Baker. Mr. Little also resigned the presidency of the road in favor of director Joseph B. Russell.

President Vreeland of the Metropolitan Street Railway Company and agents of a number of railroads and steamboat lines centering in New York are discussing the advisability of a new surface line which shall make direct connections from the Grand Central depot to the ferries of the Pennsylvania, Erie and Baltimore & Ohio.

The consolidation of street railways, under the title of the Worcester Consolidated Street Railway Company by the Old Colony Trust Company of Boston, now includes the Worcester Traction Company, Worcester and Marlborough, Leominster and Clinton, and the Worcester Suburban lines. The Worcester Traction Company securities will be retired.

All the trolley lines in Elizabeth, Rahway and Plainfield, N. J., with the exception of the North Jersey system, have consolidated under the name of the Elizabeth, Plainfield & Central Jersey Railway Company. The new company has about 60 miles of track, its capital stock will be $3,000,000 and $2,500,000 bonds are authorized. David Young has been elected president, and Thomas A. Nevins vice-president.

The Massachusetts Electric Companies has declared a dividend of $2.33 on the preferred stock, payable January 1 to stockholders of record December 15. The additional ⅓ per cent., is not in the nature of an extra dividend, but represented the amount which shareholders would have lost under the new policy of paying dividends on January 1 and July 1 instead of June 1 and December 1, if it had not been made up in this way.

The consolidation of the Brockton and Plymouth Street Railway Company, the Pembroke Street Railway Company and the Plymouth and Kingston Street Railway Company of Massachusetts is now complete. By consolidating these three roads, the first two of which have been recently constructed, the new Brockton & Plymouth Street Railway Company has a through line from the lines of the Brockton Street Railway Company to Plymouth. The company is at present capitalized for $270,000.

The Electric Storage Battery Company of Philadelphia has declared a cash dividend of 6 per cent. on the preferred stock, being the accumulations in this stock to January 1, 1901, payable January 2. Books close December 20 reopen January 3. The company also announces that the policy is to now maintain the full regular rate of 6 per cent per annum to which the preferred is entitled, which also entitles the common to receive 6 per cent. per annum. Beginning April 1, 1901, therefore, quarterly dividends on both stocks will be announced at the rate of 6 per cent. per annum.

To absorb all gas and electric light companies in Westchester County is the purpose, it is said, of "The Westchester Lighting Company," which has been formed in that county. Simultaneously on December 1 certificates of the increase of capital stock of the company from $2,500,000 to $12,500.000 were filed in Albany and in the White Plains Clerk's office. The certificate says that of this sum, $10,000,000 is common stock, consisting of 100,000 shares of the par value of $100 each, and $2,500,000 is preferred stock of the same par value per share. Directors of the new trust comprise Charles H. Werner, Louis B. Grant, Richard F. McKirney, M. J. Werner, Charles M. Hemingway, N. D. Daboll, Henry A. Kenworthy, Charles W. Squires, W. W. Scrugham and Reginald H. Giles. The papers were drawn up by former Lieutenant Governor Sheehan. It is said the new corporation proposes to erect several extensive plants through the county as soon as it obtains new franchises and rights in White Plains, Yonkers, Mount Vernon, New Rochelle, Pelham, Port Chester, Rye, Harrison, Mamaroneck, Tarrytown and Peekskill, N. Y.

Kuhn, Loeb & Company, announced on December 1, that on December 7 they would receive subscriptions, at 104½ and interest, for $10,000,000 of the Third Avenue Railroad Company's first consolidrted mortgage 4 per cent 100 year gold bonds. These are part of a total authorized issue of $50,000,000 of which $35,000,000 were purchased by Kuhn, Loeb & Company last spring, leaving $15,000,000 unissued, of which $13,433,000 are reserved to retire outstanding issues. The fixed charges of the Third Avenue Company and its controlled companies, inclusive of the issue of $35,000,000 of the new bonds authorized, amount to $2,095,689. It is estimated that after the completion of the electrical equipment now in progress and with the economies resulting from the close connection with the Metropolitan Street Railway Company, the annual net earnings of the Third Avenue Railroad will be at least $3,000,000. This, together with the surplus earnings of the Metropolitan Street Railway, after deducting its own fixed charges and taking as the basis the results of the last fiscal year, would provide net earnings of nearly $6,500,000 to meet fixed charges, amounting, as above stated, to about $2,000,000 in all.

EDITORIAL NOTES.

"Electricity's" Educational Series.

In this issue will be found the fifth article of our educational series, entitled "Storage Batteries." This article needs no commenting on as it speaks for itself.

This series so far has proven a success, judging from the number of subscriptions we are daily receiving from as far West as California, and as far South as Texas. As we anticipated, there is a demand among practising electricians for articles of a practical nature that explain in a simple and clear way the problems that have taken such men as Maxwell, Lord Kelvin and others years to solve. Such a series we have been fortunate in being able to present to our readers, and are gratified that it has met with universal approval.

* * *

Developments in Wireless Telegraphy.

Various developments have taken place in wireless telegraphy of late, which may in the near future make that method of transmitting messages invaluable to the commercial world. We refer among other things to the improvements Mr. Marconi has made in his transmitter and receiver. He has done away with the vertical wires, substituting low cylinders for them, and with this new arrangement has succeeded in sending messages over considerable distances. The transmitting of a message over ninety miles is no longer considered an achievement of note, as may be inferred from a recent report of the United States Consul at Brussels to the State Department. A station has been established at La Panne, Belgium, for the exchange of wireless telegraphic messages between Belgium and England. The Dover-Ostend mail boat Princess Clementine was fitted up with temporary apparatus for use in experimental trials. The test showed that messages could be transmitted with the same regularity and celerity as ordinary telegrams. Various messages were sent from the vessel to Ostend, Brussels, Dover and London, and the reception of each was acknowledged promptly. Subsequently, the Consul adds, a message was sent from the vessel to the station at Dover Court, Essex, a distance of almost ninety miles, including many miles of cliffs and sea.

The most startling development, however, is the statement recently made by one of Mr. Marconi's assistants, that inside of a year it would be possible to transmit wireless messages across the Atlantic. This, it is claimed, will be possible owing to improvements made by Mr. Marconi in his apparatus. A full explanation of his alleged new discovery has not yet been given out, but the Italian inventor is said to have announced positively that it is entirely successful, and that all submarine cables will be done away with, and the cost of ocean telegraph messages reduced to a nominal sum.

As might be expected such an announcement is something of a surprise, and has had the effect of somewhat dampening the ardor of the advocates of the Pacific cable project. If Mr. Marconi can in the course of a year or two so perfect his apparatus that it will be possible to send wireless messages two thousand to three thousand miles, what is the use of having Congress appropriate some $12,000,000 for a submarine cable to the Philippines, when a set of Marconi instruments may be procured at the most for $10,000? This is the question that is being asked.

Although we have no desire to appear pessimistic, it is a well-known fact that a child has to learn to creep before it can walk, and that this same principle applies to every great invention that has ever been brought out. Improvements in the telephone, the locomotive, the dynamo and almost everything else were made gradually and slowly and not by leaps and jumps, and in our opinion wireless telegraphy will be no exception to the rule. As one hundred miles is about the longest distance over which a wireless message has ever been sent after years of labor, it is scarcely likely that one year, two years, or even three years, will see this distance multiplied by twenty.

* * *

Two Thermal Storage Systems.

The New York & Putnam Railroad is about to try an alleged new system of storing power. While the details have not been made public it is known that in a general way the process consists of a method of subjecting water to a high pressure, while heat is being applied, and making use of the superheated steam thus generated for propelling cars. The daily press hails this scheme of storing power as a wonderful new invention, whereas, from the information at hand, this process differs little from that known as the Halpin storage system, made use of at Shore-

Digitized by Google

ditch, London, and which was referred to in these columns as far back as August 25, 1897.

The objective purpose of these two methods of storing power differs entirely. As stated above, the system about to be made use of in this country is intended for the propulsion of railway cars, thus doing away with the present locomotive, fire-box and tender. This is to be accomplished by means of specially devised motors on the cars, and by an ingenious arrangement by which the superheated water is released drop by drop from a reservoir under the car into a high pressure cylinder, where, owing to the pressure being removed, it bursts into steam and operates a piston.

The Halpin thermal storage system, on the other hand, is made use of in England in connection with refuse destructors for storing power during the day when the steam and electrical plant is not in operation, in order that the energy in the form of steam may be utilized during the night at any desired rate. It might be in place to state that the energy thus obtained is made use of in most cases for operating engines and dynamos to obtain current for lighting purposes.

Mr. Halpin has proposed three systems, which are severally known as the "steam storage," "feed storage," and "combined feed and steam storage," in all of which he employs large iron storage cylinders filled with water brought to the same temperature as the water of the boilers by means of connecting pipes between the two through which a constant circulation is kept up.

In the steam storage system he employs only sufficient boiler capacity to supply the mean demand on the station and storage tanks sufficient to supply the maximum demand. The boilers thus work continuously at their most economical rate, storing up heat in the tanks during light load in sufficient quantity to take care of the excess demand at busy hours. The water thus heated, when fully charged, is under a pressure of 265 pounds per square inch, which corresponds to a temperature of 406° F.

Thus it will be seen that the thermal storage system, which has been made use of in England for several years, does not materially differ from that recently tried on the New York & Putnam Railroad, except in the use made of the steam.

* * *

Features of the South Carolina Interstate Exposition.

Among the many and attractive displays at the coming South Carolina Interstate and West Indian Exposition to open in Charleston on December 1, 1901, and extend into the middle of the following year, will be the electrical display, exhibits and equipment.

It is the intention to beautify the already natural beauty of the landscape in every way possible, and in order to aid in this matter electricity will play no inconsiderable part. Among other features an artificial lake will be constructed, and in this lake will be the electrical island, upon which will be erected the Palace of Electricity, one of the most unique and effective of structures, with an electrical fountain, cascades and every known modern appliance of electricity which can be utilized for the purpose.

One of the buildings has already been completed, and although it was designed and erected in a very limited space of time, yet it is perfect of its kind, rich in coloring and harmonious in outline, admirably adapted not only for the immediate purpose for which it is to be utilized, but also for its final destiny as one of the brightest ornaments of the Exposition. It is in the form of an octagonal booth, the framework composed of light malleable iron, the exposed surfaces inside and outside of the building being filled in with beautifully inlaid mosaics of rare marbles, onyx and glass. The dome of the booth is of leaded glass, representing in colors the globe of the western hemisphere, Charleston being indicated by a blazing jewel of light. Below this dome is a frieze of jewelled glass, containing typical motifs in swags and arabesques, which, like the dome, is lighted from within by electricity, the whole being supported upon eight strong, graceful columns and arches of inlaid mosaic. Above the capitals of these columns are beautifully molded swans, with extended wings, the shining globe, with its dividing lines of longitude and latitude, and these winged creatures together inevitably suggest a floating and moving spirit, the entire structure being symbolic of light, motion and progress. Viewed from within or without, this little building is equally radiant and transparent. Between the glass sides of the columns and the frieze, as well as in the dome are myraids of concealed electric lights, throwing out a prismatic halo, while, still further to enhance the beauty of the effect, sprays of water play around the dome, frieze, columns and arches, affording a constant kaleidoscopic change of color and form.

Within this booth a fountain of onyx and glass rises from a strong, substantial base, the figures on the pedestal representing the triumph of electricity over water power. The cylindrical shaft copies, in conventional lines, the trunk of the palmetto, and at the top of this column a beautiful statue of Columbia stands upon a large mosaic ball, amid a cluster of palm leaves. This statue is supposed to be typical of the New South. In one hand she holds a distaff, outlined in flashing currents of electricity, and suggesting the cotton industry, while in the other hand she bears a dazzling arc lamp, which typifies the light of progress. Below the water line of the fountain and the sprays of water which are cast up from the grotesque projections, like the gargoyles of mediæval architecture, are mirrors and lights which duplicate, with magical effect, the radiant coloring and enchanting lines of the dome and columns. Both the booth and the electrical fountain are so constructed that they can be taken to pieces and shipped from one place to another if necessary.

It is stated that President McKinley's proposition for an accurate determination of the meridians of the Yukon, is made feasible owing to the construction of telegraph lines in that region by the Canadian Government. A line from Ashcroft to Atlin, British Columbia, was started last summer, and will be finished next spring. It connects with a line from Bennett to Dawson, which was strung last year. From Dawson, the line has been extended to Forty Mile Creek. These telegraph facilities permit the accurate determination of longitude. The matter is one of the exhange of time. Between Ottawa and Vancouver the time was fixed some time ago. Vancouver will form a basis for exchanging the time with some northern point in the Yukon, and when that is done, the time between such northern point and the capital of the Dominion can easily be exchanged. The astronomers will then get the difference of time between Greenwich and the Yukon, or in other words, the longitude.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Roentgen Society of the United States will hold its first regular meeting in this city, on December 13 and 14, at the Academy of Medicine, 17 West 43d street. A number of interesting papers will be read and discussed. Dr. S. H. Monell, 47 West 27th street is chairman of the committee of arrangements.

Consul Hughes at Coburg, Germany, makes a report to the State Department at Washington, D. C., in regard to the various attempts that have been made in Germany to devise a means to counteract the destructive influence exerted by the passage of heavy electric tram-cars upon asphalt pavements. "Hitherto," he says, "these endeavors have been without definite results, but that much has been said lately in praise of a system which is shortly to be subjected to a practical test in Berlin. Contrary to ordinary practice," continued Consul Hughes, "in which the tram rails are laid immediately upon a foundation of concrete and in direct contact with the superimposed asphalt, the new method consists in laying the rails upon a bed of coarse gravel and running a line of hard wood blocks along either side. Experience has shown that ordinary pavements, with gravel and stone foundations in place of concrete, offer the greatest resistance to the influence of electric cars. It is assumed that the gravel or stone allows the rails more play, which is advantageous in that despite great care in their manufacture, it is impossible to insure exact uniformity in the gauge of the cars. The new method is also relied upon to reduce the noise caused by the cars running over the lines."

An Ohio man is evidently making good use of his electric automobile having arranged it so that when he comes in from a trip he can quickly make connections and light his stable from the auto's batteries.

Prof. V. L. Emerson, of Ottawa, Ont., has just completed the invention of a new incandescent light. Generally speaking, it is a hydrocarbon light in which each burner is independent and so arranged that the heat generated in burning becomes the agent which produces the gas that sustains the light. Kerosene oil is carried through a small hollow wire to the burners which may be attached to ordinary gas fixtures. The lamps are handsomely made of burnished copper and the oil is completely sealed in bulbs of the same material. The apparatus can be handled without the slightest danger of explosion, is portable and self-contained. Several different systems of this new light have been completed. The burners are so arranged as to force in air that, when combined with liquid carbon, a mixture of gas capable of great heat and lighting power is produced. The system has been adapted to street, factory and dwelling house lighting, also to cooking and heating purposes.

One of the schemes which will come before the British Parliament next year contemplates the construction of a tunnel under the Solent

Digitized by Google

from a point near Hurst Castle to the Isle of Wight. An independent company, powerfully backed, it is said, has the enterprise in hand, and the bill which comes before Parliament seeks, first of all, powers to construct a railway from a point in the parish of Sway, on the Brokenhurst and Lymington line, to the Solent. From Hurst Castle the new railway will, by a gradual descent, reach the tunnel, which for the first portion will be constructed of tubes, larger but similar in design to those on the electric railways of the English metropolis. Later on, as the railway gets well below the sea-bed, the tunnel will be of brick and cement.

ACCORDING to the London "Electrical Engineer," the "West Sussex Gazette" is responsible for the following interesting note: "What is a 'milking booster?' Some members of the Worthing Corporation are curious to know. They have ordered two for their electric light undertaking, and don't believe in buying pigs in pokes. The chairman of the special committee was asked for a definition. He says a 'milking booster' occupies the same position at electric lighting works as champagne at a public dinner. A prominent teetotaler who sits on the council thinks that, if such is the case, the town might spend its money much more profitably than on 'milking boosters.'"

A WRITER to the London "Times" of November 29, relates the following entertaining incident: "At the Zoological Gardens on Saturday I witnessed an unrehearsed incident in animal life which is, perhaps, worth noting. A large electric eel was swimming in its tank with more activity than usual, these being generally sluggish creatures, when one of the big foreign cockroaches now established as a kind of pest in the houses where a high temperature is maintained dropped into the water. It began to swim vigorously across the tank, spreading out its wing cases and making a disturbance on the surface of the water. The eel turned round, swam past it, discharged its battery at about 8 inches off, and the cockroach instantly stopped stone dead. It did not even move its antennæ after. The eel afterwards swallowed it, though I imagine that cockroach, even when electrocuted, cannot be palatable. But it is not a little curious that a fish weighing at least 12 pounds, should choose to fire its heavy artillery at an insect 1¼ inches long instead of swallowing it sans facon.

AT the present price of coal, says the "Oesterreichische Zeitschrift fuer Berg und Huettenwesen," the use of turf as fuel commands our special attention. Hitherto all attempts to use turf as fuel and for the production of gas on a large scale have failed, for the reason that no means existed to dry it cheaply and quickly, nor could it be pressed into a small volume. Turf contains about 75 per cent. of water, of which it loses very little in ordinary "drying." It is now proposed to reduce the turf to pulp and destroy the fiber after which the mass is easily dried, getting quite hard and furnishing an excellent charcoal.

A SECTION of the Italian Adriatic Railway is, says the "Colliery Guardian," London, about to be worked by polyphase motors, the current to be delivered to the motors at a pressure of 3,000 volts. The power station will be at a fall on the River Adda, where electric currents will be generated at 20,000 volts three-phase alternating, and transformed at stations on the line to 3,000 volts, and delivered to the motors from double-trolley wires overhead in the usual way. The currents will be worked at a periodicity of fifteen per second; that is to say, there will be fifteen complete cycles per second, as against 40 to 100 cycles common in England, and twenty-five at Niagara Falls. The lower frequency of the alternations will give greater economy, but it will cause any lamps which are on the same circuit to wink. Probably a special provision will be made for this. The railway is apparently to be worked on the independent unit system, in which each car carries its own motor, as against the plan adopted on the London electric railways of placing all the power on a separate locomotive car. Each car will have two three-phase motors of 150 horse-power.

THE Department of Bridges in Brooklyn, N. Y., has lately put in a new capstan at the Washington avenue bridge, crossing Wallabout Creek. This will do away with all the trouble which boats have experienced in the past in getting through the draw because of a heavy current on an ebb or flood tide. Electricity has been substituted and will be used as a means of pulling the boats through the creek at this point.

A LONDON contemporary states that the Roumanian Electric Company has commenced to transmit power to the Bustinari and Campina oil centers from its central electric station at Sinaia, Roumania. During the past month, four of the oil wells of the Steana Romana Company have been worked by electric power. The line pressure is 11,000 volts. At Campina the current is transformed down to 500 volts, and distributed to the motors. The experience of the last month has proved so satisfactory that the Steana Romana Company has decided to alter its entire installation and to replace steam engines with upwards of 100 motors. They estimate that the substitution will cost about 2,000,000 francs, that the cost of working will then be reduced to one-half, and that the saving of time will amount to 33 per cent. Another and very important advantage that will accrue from the substitution is the reduction of the risk of firing the wells, a risk always accompanying the employment of steam boilers near wells which may spout.

MR. R. W. ALLEN, of Queen's Engineering Works, Bedford, England, on his return from a recent trip through this country writes to the London "Times" as follows: "I visited most of the principal electric construction companies, engine builders, tool makers, locomotive works, steel works and electric power plants, and in every case and everywhere I saw how far and away advanced they are over us in methods of construction, design and magnitude. One electric power station in New York alone has 66,000 hp., and their success is due to the extraordinary care and attention which are given to every minute detail, not one point being missed. . . Unless we radically alter and improve our system generally, we shall be left far behind. . . . It is not only in engineering we are behind; it is the same story in many branches of industry. . . . If the British employer would only admit that he is beaten, endeavor to reorganize and make a fresh start, I believe we might yet hold our own and regain much of the lost foreign trade."

ELECTRICITY is rapidly replacing steam and compressed air in mines all over the country. One after another is taking up that kind of power, and it seems as if within a short space of time most of the underground work would be carried on by electric force. There is no doubt of its cheapness for drills as compared with the other kinds of power, and it certainly is much more convenient. To bring steam or compressed air to the heading of tunnels sometimes many hundred feet underground, it has been necessary to build long pipe lines, and to meet with delays through broken joints and many other accidents which are likely to happen to pipe lines. On the other hand, the electric-power wires are flexible, do not require to be laid in any particular way, and are always ready for use,

AMONG the many electric novelties is a small clock mounted on a wooden box containing a storage battery. Set in the top of the box in front of the clock is a tiny electric lamp with a switch handy. Whether the clock is placed at night on a stand by the bedside where it can be reached by stretching out a hand, or whether it is left on a mantel, a turn of the switch throws a bright light on the face of the clock, whenever it is desired to know the time. The storage battery contains a supply of electricity sufficient to last for months.

The "Paris Figaro" states that a project exists for constructing a moving platform on the right bank of the Seine. It will be underground and its length will be about ten kilometers. The route proposed passes under the Avenue de l'Opéra, the great boulevards, the Boulevard Sébastopol, the Rue Turbigo and the Rue de Rivoli. In place of the three platforms now existing at the Exposition the new scheme embraces four. The first, as at the Exposition, will be stationary, the second will have a velocity of 1.50 meters, the third 3 meters, and the fourth 5 meters. Thus a very rapid means of transit a-foot will exist in that portion of Paris, now the most encumbered by vehicular traffic, for as all locomotion will be in one direction a person walking fast on the fourth platform, having no adverse stream of pedestrians to avoid, will easily be able to do more than ten miles an hour.

The New York Electrical Society.

The 210th meeting of the Society will be held at the College of the City of New York, 23d street and Lexington avenue, this (Wednesday) evening, December 12, at 8 o'clock.

Dr. Samuel Sheldon will lecture on "Electrical Measurements of Precision."

This lecture will include: 1. Recent improvements of methods for measurements of precision. 2. Distinction between commercial measurements and those of precision. 3. Distinction between absolute measurements and those of comparison. 4. Present standards. 5. Methods of comparing standard resistances of all magnitudes. 6. Methods of comparing EMF.'s 7. Current measurements, 8. Standard luminants and their comparison. The following standards will be exhibited: 1 ohm, 0.01 ohm, Reichsanstalt Clark cell, Carhart cell, Reichsanstalt compensation set, Hefner-Alteneck lamp, improved Lummer-Brodhun photometer screen. After Dr. Sheldon's lecture, some remarks will be made by the President on "Lighting at the Paris Exposition," with some night views.

ARTICLE NO. 5.

STORAGE BATTERIES.

In article No. 4, we took up primary batteries and in a general way gave an account of the conditions productive of electricity by chemical action. We will now talk for a while on another style of batteries, called secondary or storage batteries; these are also productive of an electric current by chemical action but the conditions necessary for this are first made or produced by electricity.

Although storage batteries have been in practical operation for a number of years they are as yet not clearly understood by the general public. As a matter of fact the opinion prevails to a great extent that a storage battery is some kind of box or jar where electricity is stored up and let out and used as required. This misleading impression is to a considerable degree due to the name "storage" which would seem to imply that the actual current was stored in some manner. I have met men working in the electrical business who could give no other explanation than that the original current was contained in the cells.

Storage batteries produce electrical action by chemical action but the condition which is productive of or governs that chemical action is first produced by electrical action.

To explain in a simple way the action of a storage battery let us take for an example a gravity battery (explained in article 4) that has been almost entirely worked out and connect to it a circuit over which a current is flowing so that the current will flow through, the cell in an opposite direction to the current produced by the cell itself. In other words, connect it so that the current will flow through the cell from the copper to the zinc. This current passing through the battery will do work, it will separate the zinc, which as it were is diffused in the solution, and deposit it as metallic zinc on the zinc plate of the cell. This is just a reverse action to that which goes on when current is being used from the cell, for in that case the action deposits pure copper on the copper plate while the zinc is being wasted away. Now you see the tendency is, in sending the current through this cell, to restore the original condition of it, or, in other words, counteract the conditions going on and produced when current is being used from it. Now the energy of the charging current is used up in producing a condition that will in turn generate electrical energy. This is just what occurs in a storage battery when it is subject to charging and discharging operation. Of course the storage battery as we know it to-day has different elements than those we just spoke of in the gravity battery, as they, used in this way, would not give very efficient results, although serving as our illustration.

Commercial storage batteries are usually made with lead plates immersed in dilute sulphuric acid. The chemical action which goes on in these when current is being passed through the cell or used from it roughly consists in transferring oxygen, which exists in oxide of lead, from one plate to the other. The plates are generally arranged in such a manner that they will contain a great amount of oxide of lead. This is frequently accomplished by perforating the plates and filling the perforations with a paste which consists of lead oxide moistened with sulphuric acid. Sometimes the oxide is formed by charging and discharging the cell a number of times; this process is called forming, and plates made in this manner are often called Planté plates after the original inventor of the lead plate storage battery who used this method of forming the cell.

To procure a large amount of capacity in a cell a number of positive and negative plates are placed in it alternately and connected in parallel, that is, all the positive plates are connected together ending in one terminal while all the negative plates are connected together ending in another terminal. The result produced by this means is that the current producing capacity of the cell will be equal to the individual capacity of each plate multiplied by the number of plates. Do not confuse the current capacity of a cell with the pressure, because the voltage does not depend upon the number of plates, but remains the same regardless of how many are used and only the capacity in current is effected by adding additional plates or increasing the size of the cell.

The electro-motive force or pressure of a lead plate cell varies from slightly below two volts to slightly above depending upon the condition of the charge. The negative plates in this style of a battery have a grayish color and the positive a deep brown when in normal or proper condition.

The storage battery just described although not the only kind known is the type most generally used and the one with which most electricians are familiar.

The use and care of the storage battery is we consider of a great deal more importance to the average electrician than the details of the chemical combination. We believe that a much greater percentage of the troubles and bad results encountered by the use of these batteries is due more to inefficient and incompetent maintenance and care than to their make or construction. Being convinced of this we will now take up the instructions necessary to be followed in setting up and maintaining a "bank" of these batteries.

When setting up a battery or set of batteries place the elements properly in the jars using great care to see that the insulating rings or bushings which separate the plates are in their right place and properly secured. When this is done the acid may be added, first making sure that it is of the proper density by using a hydrometer, which if the solution is correct and contains the proper proportions of sulphuric acid and water, would indicate 1,200 degrees specific gravity. After the solution is added to the cells if it be measured again with the hydrometer, it will be found to have dropped from 1,200 degrees to about 1,180.

The battery should not be allowed to stand but the charging current should be applied at once and in such a way that the positive conductor of the charging circuit be connected to the positive terminal or plates of the battery. The rate of flow must of course be governed to conform to the size of the cell being charged and the instructions supplied by the company who manufactured it followed in this respect. However if this is not furnished divide the current capacity of the cell by twenty, which will give approximately the normal or safe rate of charge. The charging should be continued until the potential will have reached 2½ volts per cell. The specific gravity of the solution, which fell shortly after the cells were filled, should now have reached about 1,200 degrees and at this point the charging rate should be reduced about one-half and continued until the voltage of the cell, or each cell, again reaches 2½ volts. When in this condition the regular service of the battery may be commenced, and on subsequent charges the voltage should be brought up to 2.6 per cell when charging at the normal rate, or if only charging at half that rate they should be brought to 2.5. Understand that the voltage in all these cases should be taken while the charging current is being applied.

When using current from a battery it should never be allowed to get below 1.8 volts per cell and then should not be permitted to remain in that condition any length of time but the charging current should be immediately applied.

GENERAL INSTRUCTIONS

Voltage is not the only indication of the condition of charge of a cell, one that is fully charged will gas or "boil" violently when charging at the normal rate.

When fully charged the specific gravity should be no less than twelve hundred degrees after the charging has been discontinued.

In a cell of good condition the positive plate should be of a deep brown and the negative of a bluish lead color.

Lack of charging if continued long enough will result in sulphate forming on the plates which is indicated by white patches. In this condition no time should be lost in applying the charging current and allowing it to continue, after the cells are apparently fully charged, at about half rate until the sulphate entirely disappears.

Always add pure water to the solution to make up for loss by evaporation, which however should not be added in large enough quantities to reduce the specific gravity to any considerable extent. The solution should never be allowed to get below the top of the plates.

Where a number of cells are used, voltage and specific gravity readings of each cell should be taken quite frequently so that any variation from the proper figure, of any individual cell may be noted and the remedy applied. About the only form of trouble that is likely to occur in an individual cell, in a bank of cells, is a complete or partial short circuit between the positive and the negative plates. This will be indicated by low voltage and low specific gravity and should be at once remedied. The most probable cause of this condition is the lodging between the plates of some foreign article or a loosened part of the plates themselves. Generally speaking a cell may be considered fully charged when both the positive and negative plates have been gassing freely for 15 or 20 minutes.

To prepare dilute sulphuric acid, always pour the acid into the water, never the water into the acid.

It is very advisable to have glass covers placed on the tops of all cells, as a very large proportion of the evaporation will condense on the glass and drop back into the solution. It will also prevent to a great extent so much gas accumulating in a battery room, which makes

Digitized by Google

the maintenance of a heavily worked set of batteries so objectionable.

To discontinue the use of a battery or take it out of service, first charge it fully then siphon off the acid, filling each cell with water as soon as it is empty. When all are full of water discharge the battery at the normal rate to less than one volt per cell, then remove the elements from the water and allow them to dry.

POINTS FOR REVIEW OF ARTICLES 4 AND 5.

What is polarization of a battery? What prevents it.

Why is carbon used in some primary batteries instead of copper?

What are three ways of preventing polarization?

How do you find what the normal or safe rate of charge of a storage battery should be?

Why are a number of plates placed in a storage battery and connected in parallel?

Explain the difference between secondary batteries and primary batteries.

Article No. 6 will be entitled "A Day With a Wireman".

PRACTICAL METHODS OF OVERCOMING THE VIBRATIONS CAUSED BY MOTORS.*

BY SHERARD COWPER-COLES.

About two years ago the writer's attention was drawn to the question of finding some means for running motors, dynamos and motor transformers in upper floors of buildings without causing any noise and vibration, as several actions had been brought against tenants of flats and offices for causing noise by the running of motors.

A number of experiments were tried, using felt, rubber buffers and washers, cork, and felt

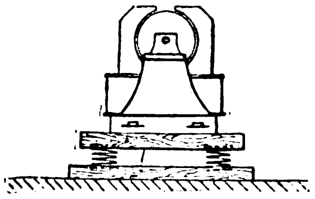

FIG. 1.

interleaved with lead. Placing the motor on a thick bed of sawdust or coffee husks, or some similar soft and comparatively elastic material was also experimented with. None of these methods were found to entirely remove the nuisance but only to reduce it.

Placing the motor on springs, as shown in Fig. 1, was then tried, and this was found to be entirely satisfactory. The machine was not bolted to the floor, but the wood frame on which it was placed was merely allowed to res on the springs, suitable recesses being cut to prevent lateral movement. The experiments were first of all made on a 1½ hp. motor, run at a speed of 1,450 revolutions per minute, used for driving light machinery in a room over some residential flats and offices, on a badly constructed wooden floor. This machine was mounted on springs, as shown in Fig. 1, and a heavy weight was placed on the motor, so as to counteract the pull of the belt. The motor has been running daily, and not a single complaint has been received since this system was adopted. Heavier motors have been mounted as shown in Figs. 2, 3, 4 and 5, and small motor transformers are suspended on springs, as shown in Fig. 6.

Since writing the above, the author's attention has been called to a paper read at the Engineering Conference of the Institution of

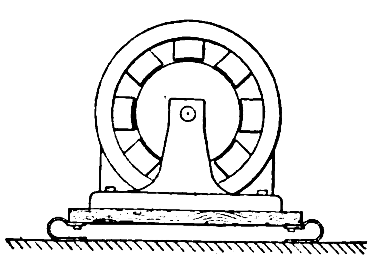

FIG. 2.

Civil Engineers, held in May, 1897, when Mr. James Swinburne read a short paper entitled "Should Generating Plant be Mounted on

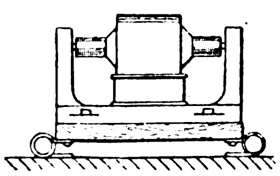

FIG. 3.

Springs?" Reference is made to a small dynamotor which was mounted on springs and placed on the top floor of a house; no particu-

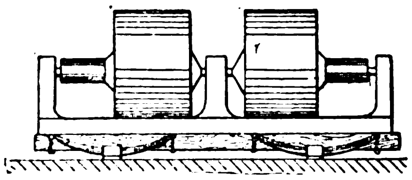

FIG. 4.

lars are given as to the method adopted, but the cure was an effectual one. Mr. Swinburne mooted the idea of mounting dynamos and

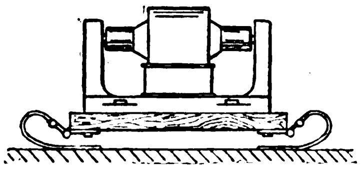

FIG. 5.

motors on springs in an article which appeared in "Industries" in 1892. Mr. W. Beaumont has done some good work in connection with

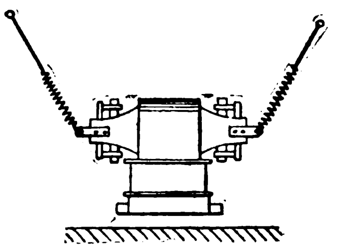

FIG. 6.

this subject, and has introduced his "vibromotor" principle, which is simple. "If a gear wants to wobble, let it wobble."

*From the "Electrical Review," London.

Preparing for the Advent of Automobiles.

Proprietors of cabs and cab drivers of Naples, Italy, are waking to the spirit of the times. They have formed themselves into an electromobile company for the purpose of transforming the hackney coaches and carrozolls into automobiles within three years, their desire being thus to forestall any foreign society that might introduce the new mode of locomotion.

MATERIALS USED IN THE CONSTRUCTION OF MARINE DYNAMOS AND THEIR ENGINES.*

BY ALTON D. ADAMS.

High efficiency, satisfactory operating qualities and reliability are prime requirements for marine dynamos and their engines. Next to these, the most essential characteristic of engines and dynamos for use on ships are small bulk and weight per unity of capacity. How pressing are these last-named requirements may be gathered from the fact that in merchant ships a considerable, and in war ships an even larger, percentage of the displacement beyond that of the hull is taken up by the necessary operating machinery.

Almost the entire construction and equipment of ships, except the electric plants, has been the subject of long study and careful experiment to determine the materials best suited for the purpose, and no reasonable expense has been spared in high-class war and merchant vessels to produce the best possible results. In the past it has been the most common practice on the part of both private shipbuilders and Governments, to accept what has been offered by dynamo and engine makers, so far as weight and bulk per unit of output are concerned. It is true that some restrictions have been put to the weights of electric generating sets, but these have only been such, in most cases, as good apparatus made for use on land could meet. The growing importance of electric equipment on ships and its applications to auxiliary power purposes seems certain to result in more exacting requirements as to weight and bulk.

Good design is able to meet the usual conditions as to efficiency, operating qualities, and reliability in dynamos and engines with the structural materials and shapes generally employed, but when bulk and weights are restricted, the kinds and shapes of the materials used are at once involved. The reason for this is found in the fact that structural materials for both engines and dynamos differ widely among themselves in their most important qualities. The characteristics of dynamo materials that have the most important influence on weight and bulk are those of magnetic and electric properties and mechanical strength. Most important of these properties is the magnetic, because of the wide variation among the available materials in this respect, and its large influence on the requirements as to mechanical strength and electrical factors. In the largest and heaviest parts of a dynamo the dimensions necessary to secure desirable magnetic qualities are much in excess of those required for mechanical strength, even where the best available materials are used. It is therefore highly important, where small weight and bulk are necessary, that the magnetic and electric parts of dynamos be of the most suitable materials.

To determine what materials are best suited for use in the several parts of dynamos, the purpose and action of each part should be considered. Taking up first the armature or receiving part, complete, it is found to consist of four essential elements—the shaft, core, windings and commutator. An armature shaft may be forged in one piece with that of its connected engine, but is more usually connected by coup lings. In either case there are no require-

*From "Marine Engineering."

Digitized by Google

ments to be made as to its magnetic or electric properties, the main necessity being for mechanical strength and stiffness. To ensure the desired mechanical properties in a dynamo shaft of the least practicable weight its material and form should be minutely specified. Dynamo shafts should be forged of hard steel, having about 0.5 per cent. of carbon, and should be hollow, as hollow shafts are much lighter than solid ones for given length, dimensions, and strength. The largest and heaviest parts of an armature is its core, which in practically all cases is built up of wrought iron or very mild steel disks, either of which is suitable for the purposes of light weight when of the proper quality. Armature cores are especially designed to meet magnetic requirements, and their mechanical strength is commonly far beyond any possible demands upon it. Magnetic properties of their iron or steel disks, and the construction of armature cores as to ventilation materially affect their weights for given capacities, but it is hard to cover these facts save by specifications of the total armature or dynamo weight.

To hold the armature core together and enable it to be assembled independent of the shaft, the disks are mounted on a spider or sleeve, and this latter is adapted to slide on and off the shaft. This sleeve or spider usually has an extension beyond the armature core at one end, and on this extension the commutator is mounted. No electrical or magnetic properties are necessary in the spider, and its important qualities are sufficient strength and stiffness for its work. Cast iron is much used for armature spiders, because it is so readily obtained and easy to machine, but its low strength to resist twisting and shearing makes it unfit for the purpose where small weight per unit of output for the armature is desired.

The best material to use for armature sleeves and spiders for marine use is soft steel castings, such as can now be had from a large number of foundries. About the only objections to be urged against steel castings for the purpose just named are their somewhat higher first cost, both as to the price per pound and the labor for machining them. The additional cost per pound of steel castings is, however, about offset by their smaller weight.

A dynamo commutator consists broadly of two distinct parts, the shell or sleeve and the segments. The shell acts simply as a clamp to hold the segments together, and is usually made of cast iron. When the reduction of weight is an object, the commutator shell should be of steel castings, as these give the required strength and stiffness with the least weight. Pure forged or rolled copper is the only fit substance for commutator segments, in spite of claims to the contrary by any who wish to sell cheap segments or dynamos with poor commutators. Cast segments are hard to produce in chemically pure copper; their electrical conductivity is lower than that of the forged or rolled variety, and they do not resist the wear of the brushes as well. For equal results in operation the cast copper segments make a heavier commutator than forged or rolled stock and they should never be used on ship dynamos.

Poor ventilation or bad proportions may result in an armature core too heavy for its capacity, and such a core increases the necessary weight of copper wire for winding it. Copper in rods or wire is the only suitable material for armature windings, and those windings with joints at only the commutator end should be preferred to those having joints at both ends. Some armature cores have a large extension at one end to act as a support for the windings, but this is unnecessary and should be avoided. The magnetic cores and poles of dynamos—that is, those parts on which the magnet coils are mounted—form large and very important portions of the machines.

Magnetic properties are chiefly considered in the size and proportions of magnet cores and poles, their mechanical strength usually being far beyond any possible requirements. So great are the differences between materials as to their magnetic properties, that the weight of magnet cores may vary as much as 300 or 400 per cent., according to the materials selected. Cast iron, wrought-iron, and steel castings, are the materials available for magnet cores and poles. The widely different results as to weight that follow the use of the these several metals for magnet cores arise from their different magnetic capacities per unit of sectional area. If the magnetic capacity of wrought iron is taken as unity per square inch, that of cast iron is about 0.4 and of steel castings from 0.8 to 1. In other words, if a wrought iron magnet core with a sectional area of 100 sq. in. will do the work for a certain case, a core of equal capacity of cast iron must have 250 sq. in., and a core of steel castings from 100 to 125 sq. in. in sectional area. The length of magnet cores is determined by the amount of wire and energy used in their coils. An increase in the area of cores increases also the wire necessary for their windings, and usually therefore the length of each core. For the case of cast iron compared with wrought iron, the cast metal being 2.5 times as large in section, and probably 1.5 times as long at least, is 2.5 by 1.5 equal to 3.75 times as great in bulk and nearly that in weight. Where steel castings are used for magnet cores the increase in weight over that for wrought iron, if any, is obviously small. Great as is the addition of weight by the use of cast iron for magnet cores, it is further augmented by the larger amount of wire necessary for windings. Cast iron was much used at one time for magnet cores, but now steel castings and wrought iron are generally used for the purpose, and should be specified in every case.

The magnet frame or part that serves to mount the magnet cores about an armature, being the largest and frequently the heaviest single part, should be carefully selected where the reduction of weight is an object. While cast iron magnet cores have been largely abandoned, the cast iron frame is still very common. The purpose of a magnet frame is twofold—to mount the magnet cores and fix them to the base, and also to furnish magnetic paths between the several cores. Owing to the attractions between the magnetic poles and their armature, the frame is subject to large mechanical strains, but its section at any point is determined in most cases by the magnetic requirements. In cases where the necessary magnetic capacity can be had with a very small frame section, an excess of mechanical strength and stiffness can be obtained by giving the frame a ribbed or flanged form. Where the weight per unit of output is not material, the use of cast iron for magnet frames may be permitted, but for marine dynamos all frames should be of steel castings, except for some simple shapes where wrought iron is available.

However carefully a dynamo may have been designed to reduce its weight, it has been the too general custom to give an iron foundry a large job on the common base for a dynamo and connected engine. The fact of course is that unnecessary weight in a base is just as objectionable as though it existed in the dynamo proper. A dynamo base is not usually required to have any magnetic properties, but must be stiff and strong. Steel castings are much the more suitable material for dynamo bases where small weight is desired, and should be used to the exclusion of cast iron for this purpose in marine work. The saving in weight by a steel casting instead of a cast iron base is often enough to compensate for the greater cost of the steel.

To rest with restrictions on the weight and materials or dynamos only for an electric plant on board ship is to leave the work of specification but one-half done, since the ordinary engine for use on land is even less satisfactory in the matter of weight than is the average dynamo. Vertical engines are the general type best suited for driving ship dynamos, because of the small floor space occupied, the ease of making direct connection to the dynamo, and the high speed of rotation at which they may be operated. In land engines, and to a large extent those for electric plants on ships, cast iron has long been the most prominent material. Crankshafts, even in some instances, have been built of much the same material—that is, gun iron, which is simply cast iron of a somewhat higher grade and with an increase of strength above the ordinary metal.

Crankshafts for dynamo engines should be forged of hard steel and hollow. In sizes too small to allow hollow forging, the shaft may be forged solid, and the interior parts subsequently machined out. Connecting rods should also be of hard steel, but instead of the regular tapered forms, rods should be machined into some of the shapes that give required strength with a minimum weight of metal. Hollow piston rods are to be preferred to solid ones in large sizes. Steel castings offer a material saving over cast iron for piston heads and cylinders in the matter of weight owing to the strength required in these parts. Cast iron engine frames have in many cases heretofore made up a great part of their weights as used for driving ship dynamos, and it is in this part of the construction that considerable improvement is possible. A number of vertical engines that have been much used for driving marine dynomos are of what is known as the enclosed type, with hollow cast iron frames that connect cylinders and bases. Such an engine is necessarily heavy per unit of capacity. Other engines have a cast iron frame between the cylinders and base at one side, and a solid steel rod or rods at the other side, but these engines must also be discarded as too heavy.

The nearest approach to a really suitable engine for ship dynamos found among present standard types is put out by several makers with four or more solid steel standards to connect the cylinders and the base. This last-named type of engine is capable of production in very low weights, when parts other than the standards are made of the most suitable materials. Some engines on the market, however, in imitation of the steel rod construction between the cylinders and base, have used standards of cast iron for the purpose. An engine with these cast iron standards is unnecessarily heavy, and is apt to be fatally weak in its frame. The most desirable construction

Digitized by Google

for light weight in that part of the engine frame between cylinders and base consists of hollow steel standards.

Instead of cast iron, the bases of engines for ship dynamos should be of steel castings, because of the large reduction in weight for given strength and stiffness effected by the use of this metal. About the only parts of engines for electric plants on board ship that may rationally be of cast iron are the piston rings and perhaps linings for the cylinders. By suitable designs with wrought steel and steel castings in engines and wrought iron steel and steel castings in dynamos, the weights per unit of capacity may readily be reduced as much as 50 per cent. for engines and 25 per cent. for dynamos below those often found in ship electric plants.

THE COMMELIN AND VIAU CADMIUM ACCUMULATOR.

Translated for ELECTRICITY from "L'Electricien," Paris, France.

This form of electric accumulator is a special type of an oxide plate or grid, to form the positive electrodes, and a negative electrode on which cadmium is deposited.

The positive electrode is so constructed as to reduce its weight to a minimum and is made up of an ebonite frame containing a lead grid, to which is riveted a conducting lead frame. This form is filled in the usual manner and afterward the active material is reduced to spongy lead peroxide, which, as a whole, makes a very light weight electrode, presenting great resistance to disintegration, especially to rapid discharges to which accumulators used for traction purposes are subject.

The negative electrode is made up of a sheet of insulating material, generally celluloid, which is completely enveloped by a sheet of lead 0.25 millimeters thick, folded on itself. Upon the two sides of the plate thus constructed are small troughs arranged in an oblique direction to the sides of the plate made up of a series of small celluloid rings forming side lines placed in rows, the distance between the rings being about 8 millimeters.

These creases are designed to facilitate the disengagement of gas bubbles and as well to hold the small particles of cadmium deposit which become detached from the plate.

The lateral and lower edges of the lead plate are covered with a coating of varnish to prevent the formation of arborescent depositions which tend to grow from the sides and bottom. The negative plates thus treated are electrolytically covered by a very fine granular deposit of metallic cadmium derived from a bath solution of cadmium sulphate.

Experiments have also been made with a cadmium deposition on carbon plates which have also given good results.

During the discharge the positive electrode acts as in ordinary lead batteries, that is to say, the peroxide of lead is reduced, while on the negative plate the cadmium is dissolved and transformed into sulphate of cadmium, which is taken up by the electrolyte solution. During the next charge the positive plate is peroxidized and the cadmium deposit obtained on the negative plate by the electrolytic disassociation of the sulphate of cadmium in the electrolytic solution. Experiment has proven that the cadmium deposit is absolutely insoluble in an open circuit.

The elements of the battery are separated by a sheet of celluloid placed between and against the positive electrode and resting on the projecting edges of the negative plate. The charged element has an electromotive force of 2.30 volts.

Following are some figures obtained from an experimental battery, which had an output of 80 ampere hours after receiving a charge of 100 ampere hours. The discharge from this battery had been allowed to continue until the difference of potential had fallen to 1.2 volts. The weight of the positive electrode in this battery was 500 grams and the two negative 300 grams.

ELEMENT OF 80 AMPERE HOURS.

Positive Plates.

Number of plates	5
Dimensions in cm.:	
Height	21
Length	10.5
Thickness	0.5
Weight of ebonite frame	22 grams.

Negative Plates.

Number of plates	5
Dimensions in cm.:	
Height	22
Length	10.5
Thickness with deposit	0.25
" without "	0.15
Weight of sheet lead 2.5 mm.	
Weight with its support	170 grams.
Weight perforated celluloid	15 "
" parchment paper	2 "
" cadmium deposited	52 "
Total	239 "
Weight of plate separator	12 "

Electrolyte.

Volume	1550 sq. cm.
Approximate weight	1800 grams.

Approximate weight of complete battery:	
5 positive plates	2150 grams.
5 negative plates	1195 "
Electrolyte, about	1800 "
Jar and connections, about	500 "
Total	5645 "

DISCHARGE CURVES.

It is interesting to note that the soluble electrode type of element behaves like a common battery and that there is no fear of sulphuration as in the ordinary all-lead accumulators, due to excessive discharge where the reduced lead from the negative side toward the end of the discharge has a tendency to be transformed into a sulphate and where the positive in its turn can be sulphurated if the discharge is allowed to continue; in the lead cadmium element the sulphuric acid liberated can always form a combination with the metallic deposit, which has been formed upon the negative plate during charging, for the resulting salt is soluble in the electrolyte. The sulphuration of the positive plate is then kept down by the dissolution of the negative plate, which absorbs all the free sulphuric acid, and consequently the discharge of the battery can be continued as long as desired, even up to the complete breaking up of the negative plate without any harm resulting to the positive plates, and further the difference of potential decreases very gradually and does not fall abruptly as in the all-lead battery where the two electrodes are reconverted from insoluble lead sulphate. This particular property of soluble electrode accumulator becomes of interest in automobile work, for it would prevent complete stoppages in driving the vehicle at a very slow pace even though the battery be almost completely exhausted and unable to furnish its usual service. Without contradiction this is one of the greatest inconveniences of electric driven automobiles and which can in this way be prevented, at the same time the lowering of the voltage, which results from the exhaustion of the positive plate, constitutes, as we may say, an automatic indication of the battery exhaustion to notify the driver to seek a charging station.

However, from the production standpoint, it has not been considered desirable to prolong the discharge to as low a voltage as 1.2 except to reserve this possible fall for extreme cases, without considering such a drop the normal working condition of the battery or as available for commercial practice.

The lead cadmium battery is a topic for further study, as it is not to be expected that the results derived from an imperfect element tested under laboratory conditions would be as desirable as practical work; but we may rightly consider from a theoretical point of view that the battery cannot be admitted to be inferior to the all-lead type, because the same identical chemical action takes place at the positive plate and the negative plates show almost 100 per cent. efficiency, but this class of battery should undergo a practical application in order to suggest these modifications so desirable to produce perfection, which will undoubtedly advantageously fit it for automobile practice.

PARIS LETTER.

Special Correspondence of ELECTRICITY.

Electric Traction in Paris.

The principal electric tramway lines have been in operation in Paris for over three months. At present there are three systems in use—the underground trolley and the contact systems of Vedovelli and Dialto. The last mentioned system has secured a franchise for not less than eighty kilometers of track and almost all the terminal stations. This installation has been constructed very rapidly, too rapidly in fact, which has resulted in frequent interruptions to the service. There are even rumors in circles supposed to be well informed that the Thomson-Houston Company has bribed the contractors of the rival line, who have the concession for the Dialto system, in order to secure poor track construction, with the object in view of making the operation of their competitors' road unsatisfactory; this seems very strange to us, and we would much prefer to believe that the system itself is seriously defective, in fact, as this system contains but one style of contact-boxes with their iron contact pin operating through a tube to make a mercury connection; it operates quite well on a level track, but when these boxes are placed on an incline, and as before, installed perpendicularly to the track surface, with the consequent result that in such a position the contact pin does not rise and fall freely through its tube, causing many irregularities, defective car-service, stoppages, and accidents to horses and people.

If these boxes are to be successfully operated on inclines they must necessarily be placed in a horizontal position with a special construction to make the surface of the box level with the street; with this modification, the contact pins

Digitized by Google

will rise and fall freely, because then they will operate in a perpendicular plane.

On the left bank of the Seine, at Paris, especially on the Boulevard Pasteur, the inclines are very steep, and a long line of cars were stopped through the defect of the system; these stoppages are very common at this particular place. There are also many complaints of accidents caused by the tramway line and cars, and not a day passes without injury to carriages and people; the companies are to blame for this in not taking sufficient time to drill their motormen. It was supposed that the old employes and car drivers could be taught in a week's time to fill these new places; obviously this is an impossibility, for on steam roads a year is supposed to be the shortest time to train an engine driver; to make a good motorman, to operate electric cars in a city street, should take at least three months.

The long-distance suburban electric roads of Paris are being built rapidly; the Société des Aciéries de Micheville has just ordered from the Thomson-Houston Company three motors of 80 hp. each.

The work on the road from the Champ de Mars to Versailles, which will be electric and operated by the Compagnie de l'Ouest, is also being rapidly constructed and the part allotted to the Thomson-Houston Company will be completed soon. The Champ de Mars sub-station is finished, while those at Mendon and Viroflay will be completed soon.

We may say that all the suburban tramway lines are finished, and that the majority are in active service, and all of them are operated by the overhead trolley system; they meet the lines of the Dialto system at the fortifications where the cars change from overhead to surface contact.

Electric Lighting in Paris.

The Paris "Official Journal" has just published a long statistical municipal report, and it may be of interest to review some of its figures relating to the actual condition of electric lighting in the Parisian capital.

The number of gas lamps still in use for street and boulevard lighting is upwards of 50,516, to which must be added 55,420 magnesia lamps of high illuminating power.

For the public buildings in the city 58,104 gas jets are required, of which the schools take 35,128, the police and fire departments, the barracks and guards 5,572, and the Mayor's office and public libraries 113; as to electric lighting 983 arc lamps are required for 45 streets, 17 parks and squares, but does not comprise the Monceau and the Buttes Chaumont Parks.

The number of arc and incandescent lamps for lighting municipal buildings is more than 20,000, including the slaughter houses de la Villette, College Chaptal, Hotel de Ville and the Halles Centrales and Mayors' office in the Tenth ward, while during the year 1898 there were only 580 arc lamps and 12,022 incandescent used for the same purpose, showing a notable increase in two years.

The total amounts paid by the city of Paris for public lighting from 1826 to 1833 was 8,400,088 francs; 1834 to 1846 was 13,330,000 francs; 1847 to 1859 was 19,700,000 francs; 1860 to 1872 was 38,600,000 francs; 1873 to 1885 was 50,600,000 francs; 1886 to 1898 was 72,000,000 francs.

The quality and intensity of the street lights have also materially improved, for in 1889 the total illumination was 75,360 carcels while in 1899 it had grown to 146,117 carcels.

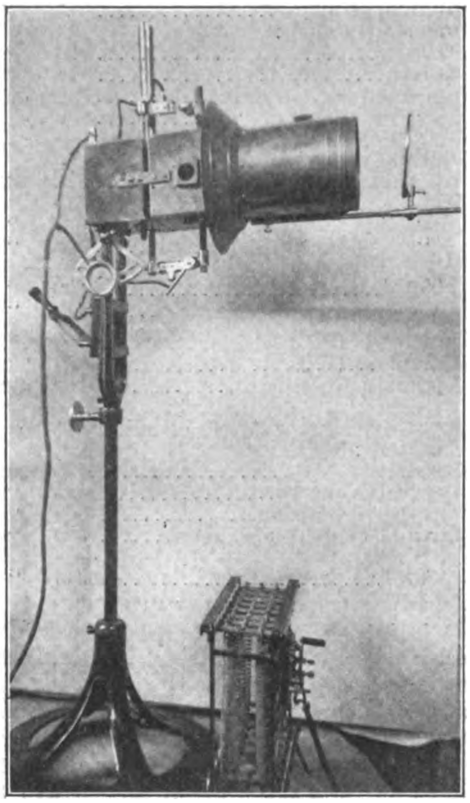
THE BLEYER ELECTRO-ARC CHROMOLUMES FOR GENERATING COLORED LIGHT RAYS.

BY J. MOUNT BLEYER, M.D., F. R. A. M. S., LL.D., New York City.

Since my experiments and discovery in 1894, that light has the power of traversing through the chest wall and other tissues of the body, both in health and disease, and its adoption by me for the treatment of tuberculosis of the lungs—I find that others have followed in my beaten track, and now make claims to it as original research. I beg to say at this opportune moment that my experimental work antedates them.

In 1896 I published in the "New York Medical Journal" some important forerunning remarks upon my undertakings in that line, and, as I say, gave out several hints, and since then have made many important chemical and physiological tests as to their powers in therapeutics.

Tuberculosis interested me most, so I dropped



Electro-arc Chromolume with Rheostat.

from my list of research many experiments which belong more properly to other domains of medicine, and I now leave to others the fulfillment of its many promises.

Prof. Finsen of Copenhagen may be ranked among the foremost of those who have successfully demonstrated facts which go far to prove the value of these rays. His institute for the treatment of skin tuberculosis by means of chemical rays of light has already gained an international reputation for itself.

A paper of special value has been read and published before the American Congress on Tuberculosis, February 22, 1900, and in "The Sanitarium," April, 1900, which dealt with many scientific facts. Therefore, I refer those who desire a more detailed account to the "Transactions" of that society and its other publications.

My specially constructed electro-arc light lamps for generating violet rays of light (color light or chemical rays), have undergone many changes since my early experiments. I found that concentration of light meant a great factor, and, therefore, more generating power was a necessity. This gave the parallel rays a much more penetrating capacity for dense tissues. I therefore reconstructed my older types, and now use the apparatus as illustrated.

Next came the question of simplicity of construction and management. I have succeeded in this undertaking after many trials. These illustrations show several types in use by me, in my daily chemical practice, which proved most satisfactory as to results. The types of lamps are capable of generating rays of the highest quality, besides the power of generation.

This test of penetration was first made by me several years ago. I now find that some one else makes a new claim to this—in other words, a re-discovery.

I showed that concentrated rays of light, as produced from an electric-arc lamp of high power, pass through the solid tissues as well as through bone by allowing these rays to fall directly upon the chest wall—and printing, as a proof of this fact, from a negative plate or film upon a sensitive plate—any subject matter thereon in less than fifteen minutes. This test, I say, has again been confirmed by Dr. J. W. Kime of Fort Dodge, and he differs in the method employed by using sunlight concentrated instead of the electric arc.

In sixty cases of tuberculosis of the lungs, I have employed these colored rays of light as an adjunct to the general treatment, with most successful issue. I find that electro-arc solarization can claim to rank as one of the greatest tonics. There are many scientific facts, regarding the chemical and physiological action upon the system, which need study, many facts which I have already studied seem to fill long-felt wants in the treatment of this disease. Of these sixty cases, I can report forty as cured, and in twenty, the disease has been arrested to such an extent as the pathological changes present admitted when they came under treatment. From my experience, I now fully believe that as an adjunct light rays in tuberculosis play a leading role. I want to stand upon these remarks for a future record. The administration of these rays must be understood from the very first, that dosage, and how given, plays an important part, and no one should attempt to use them homœpathically in any manner. Long exposure is one of the prime rules—nothing short of a half hour over the nude surface, a longer time is preferable for each sitting, over the selected area.

A simple description of these electro-arc generators of the chrom-rays and the method of employing them is essential. These lamps assume the name I gave them, "Electro-arc Chromolumes," as they are the sole producers of these specific colored rays. Their construction is so simple that their management does not require any study. They are all capable of giving from 5,000 to 25,000 candle power. This high candle power or efficiency is dependent upon the amount of current at one's disposal. High candle power is a necessity for curative purposes. There is no difficulty in getting any amount of electric current for their operation. All that is necessary is to have the room wired with an exact thickness of carrying efficiency, and then a transformer of exact size—which

Digitized by Google

any company is ready to furnish on application. My own plant is furnished with an 80 ampere current transformer—and the lamps are so constructed that either more or less current does not affect them. By this arrangement any one can change his installation according to his intended work.

Each lamp for generating these chemical rays has fitted to it one rheostat, therefore more than one generating lamp can be set in operation in the same room or elsewhere at the same time; also they can be so installed to operate on one single rheostat for special selection of any lamp desired, if more than one is in use.

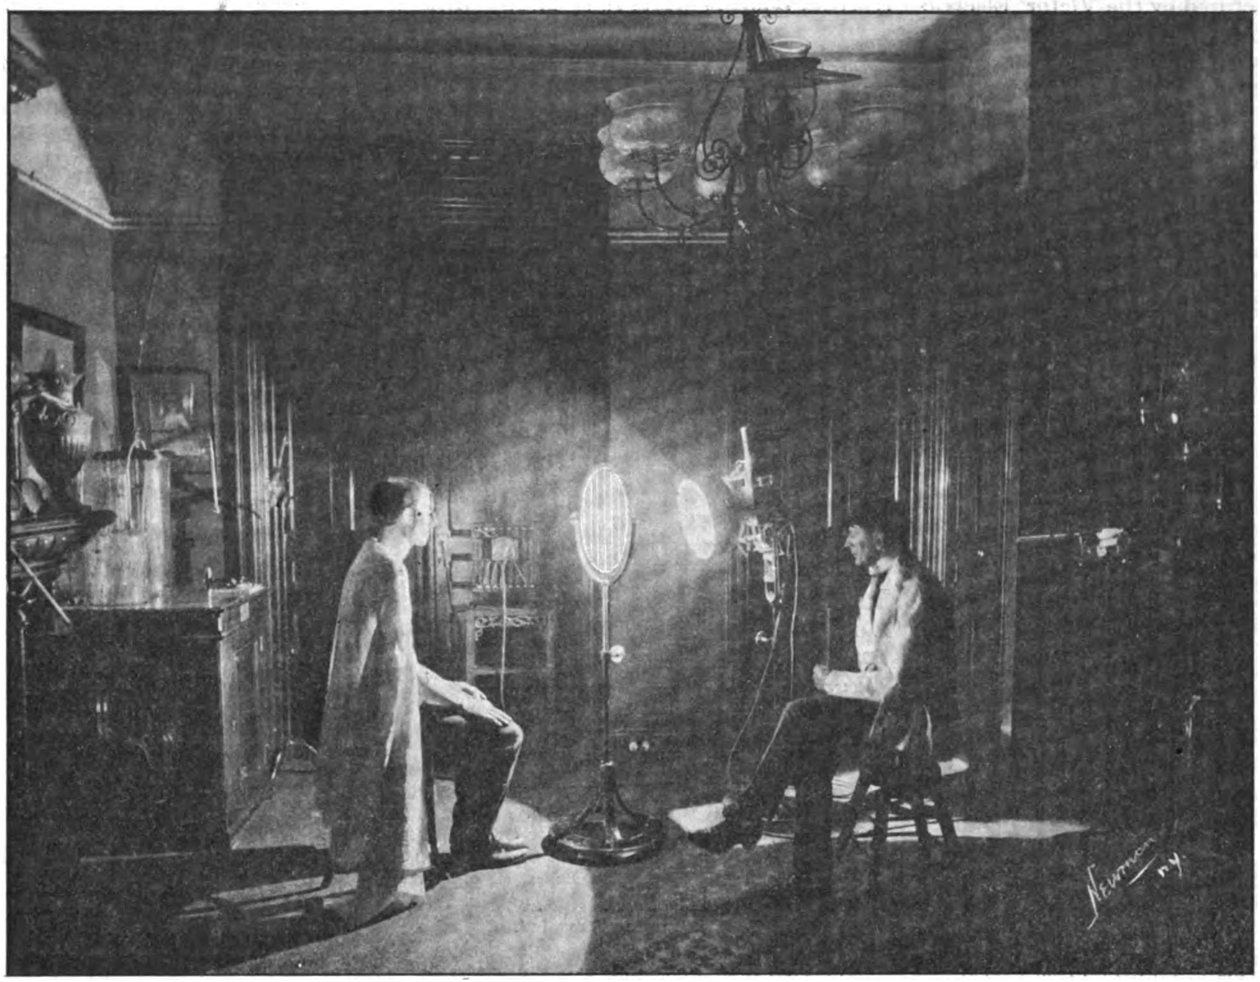
There are several different types of my lamps now on the market, which are made suitable for the different electric currents—for the high

ple of the searchlight, and has the same advantages as the other lamps.

A screen accompanies every Electro-arc Chromolume. This additional piece of apparatus is for the purpose of screening the heat rays emitted during the operation of the lamp upon a selected surface with a high concentration of the light beam for any length of time. It consists of blue glass, cut in strips, set in a framework, on a movable stand capable of many changes of position.

All these generating lamps are mounted on stands which give any angle of motion suitable for application. The entire lamp, screen, etc., can be moved over any area of the operating chamber. They have long cables attached to the lamps coming from the electric feeder of the installation.

such suitable remedies as are indicated according to the case in hand, 75 per cent. of tuberculous patients are curable, that is, curable to that extent according to the lesion or pathological changes already present at the time they come under treatment. Of course we all understand that pathological conditions, which have in certain stages of this disease left their markings, cannot be changed. We cannot give the patient any more breathing capacity after certain conditions become, so to say, stationary. Each case, however, should be taken on its own merits and treated accordingly, and only such promises can be made as accord with the state of the case. There are, however, forms of tuberculosis which can be thoroughly cured. Moreover, a large majority or percentage of these cases, should they pre-



SPREAD-LIGHT ELECTRO-ARC CHROMOLUME IN FULL OPERATION IN DR. J. MOUNT BLEYER'S LABORATORY FOR THE TREATMENT OF TUBERCULOSIS.

tension and the low tension, or the Edison direct or alternating current, and this was a most necessary point to be considered. For the high tension current I constructed a lamp which operates both automatically and as a hand-feed. This lamp, in order to get a steady and pure light spot, is provided with a set of plano convex, short-focus lenses, a moving gear for adjusting the focal lines—this adjustment being a most important device, as the focal parallel lines can be changed to the exact spot wanted. The focal spot ranges from a half inch to thirty inches of concentration. By this means any part of the apex or other portion of the anatomy can be treated accordingly. For the low tension (Edison direct current) the lamps are different; no lenses are used. The focal lines are created by a Mangin mirror, on the princi-

I have in use several of these types, and each one has its own particular value.

I present herewith an illustration of the Chromolume in full operation, taken from my earliest experimental work in 1894. This gives an idea how the light is applied to tuberculosis patients.

In concluding this article on my Chromolumes, let me say to those who will follow up this method of photo-therapeutics as an adjunct to the general treatment, that they will be most amply repaid for the trial. I wish to say it now, and what I say I am willing to stand by, that in certain picked cases of tuberculosis, there is no remedy equal to light as produced by the electro-arc, or direct solarization by the sun where it can be had. With light, hygienic food, fresh air, exercise and

sent themselves at an early stage, are curable by this adjunct treatment within from two to three months.

One important factor must always be borne in mind in the use of this method; namely, that a sufficient amount of time should be alloted to each case, not less than an hourly sitting daily.

This photo-therapy is most admirably adaptable for sanitarium and hospital purposes.

For years I have adopted a system for generating these colored rays of light. I have also shown where they are practical by the construction of solariums—these of course being more suitable to country than to city use, and also in a climate where the sunlight is in abundance.

The solariums must be constructed on

Digitized by Google

plans which provide for all contingent and important necessities—heating, ventilating, cooling, glassing with colored glass intermingled with white glass, proper exposure, etc., are some of the principles embodied in their successful employment. Exposure of the patient also plays an important part in the treatment. The entire body in a nude state should be exposed to this light for at least two hours or more daily.

In our entire category of remedies, I know of none that can touch the tonic effects that the application of this method will produce.

These Chromolumes are made for me by the Universal Stage Lighting Company, 842 Broadway, New York.

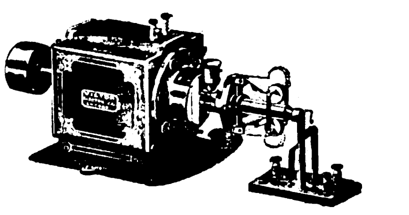
The Victor Igniter.

During the past two years the Victor $\frac{1}{8}$ hp. dynamo, manufactured by the Victor Electric Company, 420 Dearborn street, Chicago, has conclusively proven its superiority as a spark producer, having never failed where it has been given a fair trial, and there are at the present time over 500 of them in use on engines of almost every type and make.

Even a casual examination of the machine will disclose the causes of this success. It is built of good material; the bearings are long, the shaft is seven-sixteenths inch in diameter, the armature wire is imbedded in slots in a laminated toothed core, and is connected into a large 18 section standard lock nut commutator, all of which insures efficiency and durability.

The entire machine is metal clad with the exception of the brush opening.

The governor shown in cut automatically opens and closes the battery switch; a glance



THE VICTOR IGNITER.

at the cut will show the operation of this device, as the dynamo gets up to speed the governor forces out the operating sleeve, this sleeve in turn forces the middle contact spring backward, thus breaking one circuit and closing another, stopping the dynamo allows this contact spring to return to its normal position.

Where a few primary cells are used to start the engine, this switch automatically cuts in the batteries when the engine shuts down so that they are all ready to start with, and as soon as the engine gets up to speed the batteries are cut out, the dynamo then furnishing the spark.

Where small storage cells are used to start with the dynamo charges the cells at the same time that it is sparking the engine, and when the engine shuts down the dynamo is cut out and the batteries cut in ready to start.

All the switching is done automatically, no hand switches whatever being required.

The use of this device reduces the cost and care of batteries to the minimum; 4 cells of dry battery that can be purchased at 25 cents each will last at least a year as they are only used a few minutes each day. There is no danger of batteries being "run down" for the automatic switch is never careless and invariably opens the battery circuit as soon as engine is up to speed. Every Victor igniter is guaranteed for one year.

You Can With a Can.

It is a surprise to many to know that Dixon's Pure Flake Graphite can be used in an ordinary squirt can. It is nevertheless a fact, and a more convenient and efficient way for applying this wonderful lubricant cannot be found. Where the coarser flake is used the opening in the nozzle of the can may require enlarging. Only a dry can should be used. A can that has had oil in it will clog the graphite. Use a dry and new can. It will pay you to try graphite in this way.

PERSONAL MENTION.

Mr. George Chapman of this city was recently elected a director in the Electric Vehicle Company to represent John Jacob Astor's interest, as the latter is going South.

Mr. Charles E. Yerkes, son of Charles T. Yerkes, was lately elected president of the Lake Street Elevated Railroad in Chicago, to succeed Howard Abel.

INCORPORATIONS.

The Little Miami Traction Company, Xenia, O.—to construct and operate an electric road. Capital stock, $50,000. Incorporators: C. Christie, of New Cincinnati; J. P. Marion, W. D. Biddle, of Cincinnati; C. Orr, R. P. Ranney, R. L. Andrews, all of Cleveland, O.

The Arctic Construction Company, Seattle, Wash.—to construct tramways, railways, telephone lines, etc. Capital stock, $50,000. Incorporators: H. S. Peterson, W. L. Green, both of Skagway, Alaska, and A. B. Mitler of Seattle.

The Boise Fayette River Electric Power Company, Boise City, Idaho—to do a general railway and electric light business. Capital stock, $1,000,000. Incorporators: J. Spafford, H. E. Neal, J. C. Stout, E. Yanish and W. O. Stout, all of Boise City.

The Hamburg Electric Land Company, Buffalo, N. Y. Capital stock, $7,770. Directors- Lewis J. Heintz and A. J. Ross, of Buffalo, and Lorasso Fields, Rochester.

The Chambersburg and Gettysburg Electric Railway Company, Gettysburg, Pa. Capital stock, $50,000.

The New York Electric Supply Company, Carteret, N. J. —to operate electrical plants, Capital stock, $50,000. Incorporators: H. M. Suermont of Brooklyn, J. T. Brown and F. B. Hoffman, both of New York.

The American Steel Railway Generating & Power Company, East Orange, N. J.—to carry on the business of electricians, mechanical engineers, manufacturers, workers and dealers in electricity, motive power, heat and light. Capital stock, $2,500,000. Incorporators: Edward G. Johnson, Franklin D. Palmer and Joseph F. Vron.

The Colorado Springs Electric Company, Colorado Springs, Col.—to construct and operate an electric line. Capital stock, $1,000,000. Incorporators: W. A. Otis, W. P. Bonbright, L. T. Curtis, H. Hine, K. R. Babbitt, C. E. Palmer, J. A. Hayes, J. F. Burns and R. J. Rolles, all of Colorado Springs.

The Indiana Electric Company, Dana, Ind. Capital stock, $18,500.

The Central Electric Company, Grand Rapids, Mich.—to do a general electrical contracting business. P. C. Miller and W. P. Freligh will be in active control.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 4, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

662,921. Apparatus for Electric Traction. Henri Dolter, Paris, France. Filed July 6, 1899.

663,198. Clip or Support for Trolley-Wires. William H. Russell, Watertown, Mass. Filed March 20, 1900.

663,201. Car-Fender. De Witt C. Wallace, Cairo, Ill., assignor of one-half to John T. Rennie, same place. Filed April 30, 1900.

663,232. Switch-Box for Electric Railways. William Kingsland, London, Eng. Filed July 5, 1900.

663,360. Electrical Rail-Bond. William Pervenko, Kiew, Russia. Filed Dec. 30, 1899.

663,376. Electrical Railway Signaling System. Louis C. Werner, Louisville, Ky. Filed Nov. 3, 1899.

663,398. Electric Railway. Ernst Sussmann-Hellborn and Wilhelm Hornauer, Munich, Germany, Filed Oct. 11, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

662,931. Electric-Arc Lamp. Frederick A. Gilbert, Brookline, and Emil O. Lundin, Beachmont, Mass., assignors to the General Electric Company of New York. Filed July 22, 1898.

662,995. Electric-Arc Lamp. Ozro N. Wiswell, Lynn, Mass., assignor to the General Electric Company of New York. Filed May 4, 1899.

662,996. Electric-Arc Lamp. James J. Wood, Fort Wayne, Ind. Filed Dec. 4. 1899.

663,095. Incandescent Body for Electric Glow Lamps. Alexander Just, Vienna, Austria-Hungary. Filed Sept. 20, 1900.

663,346. Electric-Arc Lamp. Walter C. Johnson and Adolph Wunderlich, London, Eng. Filed Sept. 10, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

662,928. Space-Block for Armatures. Henry Geisenhoner, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Jan. 18, 1900.

662,979. Automatic Magnetic Circuit-Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company of New Jersey. Filed April 27, 1900.

662,987. Circuit-Protector. Alfred Stromberg, Chicago, Ill. Filed June 28, 1900.

662,992. Electric-Current Indicator. Henry M. Warren, Schenectady, N. Y. Filed Dec. 9, 1899.

663,039. Flush Switch Support. Charles G. Perkins, Hartford, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed June 28, 1900.

663,207. Means for Starting or Stopping Electric Motors. James J. Wood, Fort Wayne, Ind. Filed July 11, 1899.

663,075. Space-Block for Armatures. Henry Geisenhoner, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 28, 1900.

663,388. Electric Igniter for Explosive Engines. Montague S. Napier, London, Eng., assignor of one half to Selwyn Francis Edge, same place. Filed Jan. 8, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

662,984. Telephone-Exchange System. Alfred Stromberg, Chicago, Ill. Filed Oct. 18, 1899.

662,985. Telephone-Transmitter. Alfred Stromberg, Chicago, Ill. Filed Feb. 24, 1900.

662,986. Telephone-Exchange System and Apparatus. Alfred Stromberg, Chicago, Ill. Filed June 6, 1900.

662,988. Telephone-Exchange System. Alfred Stromberg and William M. Davis, Chicago, Ill., assignors to the Stromberg-Carlson Telephone Manufacturing Company, same place. Filed June 28, 1900.

663,196. Telephone-Receiver. Charles H. North, Cleveland, O., assignor to the North Electric Company, same place. Filed Nov. 15, 1899.

663,216. Railway Telephone System. Elmer E. Carpenter, Worcester, Mass Filed May 25, 1900.

663,367. Switchboard for Telephonic or Telegraphic Purposes. Charles Shore, Bolton, and Charles Heap, Caldershaw Rochdale, England. Filed Oct. 7, 1896.

MISCELLANEOUS.

662,911. Electric Heater. John E. Brown, Philadelphia, Pa., assignor of one-third to John J. Shanfelter, same place. Filed Jan. 24, 1900,

662,913. Elevator. John Bush, London, Eng., assignor of one-half to Arthur David Jenkins, Borough, Eng. Filed April 11, 1900.

663,015. Electric Meter. Thomas A. Edison, Llewellyn Park, N. J. Filed March 17, 1899.

663,043. Return-Signal Device for Call-Boxes. Joseph S. Robinson and Henry M. Robinson, Chicago, Ill. Filed Feb. 12, 1900.

663,059. Automatic Electrical Apparatus for Indicating Leaks in Ships. Vladimir W. Zvorikin and Serge de Blumenthal, Moscow, Russia. Filed March 24, 1899.

663,082. Fire-Alarm Telegraph Apparatus William H. Kirnan, Bayonne, N. J., assignor to the Gamewell Fire Alarm Telegraph Company, New York City. Filed Oct. 4, 1899.

663,130 Electrical Apparatus for Controlling Signals or Other Circuits. Homer A. Parrish, Jackson, Mich., assignor to the Parrish Signal Company, same place. Filed Aug. 11, 1899.

663,193-663,194. Phonograph. Frederick Myers, New York City, assignor to the Stylophone Company, same place. Filed Aug. 1, 1900, Oct. 12, 1900.

663,233. Connection of Strikers to Motor-Vehicles for Mechanically Operating Electric Switches. William Kingsland, London, Eng. Filed July 10, 1900.

663,289. Dry Battery. Ernest Meyer, Paris, France. Filed Nov. 10, 1899.

663,304. Magnetic Separator. Frederick Theilengerdes, Memphis, Tenn., assignor of one-half to Walter Goodman, same place. Filed June 8, 1900.

THE TELEPHONE WORLD.

Telephone Competition.

The Interstate Telephone & Telegraph Company, organized more than a year ago, to give long distance connections to independent local telephone companies in Pennsylvania, New Jersey and Delaware, held its annual meeting last week at its offices in Philadelphia. It is stated that the company now has lines in operation from Jersey City through Trenton, Norristown, Allentown, Mauch Chunk, Hazleton, Wilkes-Barre to Scranton, connecting over 10,000 telephones and 400 places. At the meeting it was decided to extend the lines west to Pittsburg and Ohio and north to Binghamton, N. Y. This will connect over 50,000 telephones, and the price of long distance service will thereby be considerably reduced. This company has purchased lines in the western part of Pennsylvania extending from Altoona to Johnstown, and is negotiating for the purchase of several long distance lines in New Jersey. The following officers were elected: C. W. Kline, president; J. P. Helfenstein, vice-president; Major Thomas Daugherty, treasurer; A. M. Worstall, secretary.

H. A. Douglass, manager of the Atlanta, Ga., Standard Telephone Company, is quoted as saying: "Some days ago there was an article published in the local papers on the consolidation of the Bell telephone interests, and intimating very strongly that the Standard Telephone Company was soon to be absorbed by the Cumberland or some other Bell company. This inference appears to have been believed by a number of our subscribers and others in Atlanta, and we wish to state positively that there is not the slightest truth in the statement in any particular. The management of the Standard Company has no intention, and never has had, of selling to the Bell. Statements and insinuations of this kind are made with the idea of creating dissatisfaction among our subscribers, and to check or stop, if possible, the steady and very satisfactory growth and advancement that we are making."

Manager J. F. Uhler, of the Chesapeake & Potomac Telephone Company, is now offering telephone service at Hagerstown, Md., at a greatly reduced price and a war with the Maryland Company seems to have started. Two classes of service are offered, one costing $24 and the other $33 a year. Either rate entitles the subscriber to a 'phone in his house and a 'phone in his business place. The rate for residences alone is $1 a month. The Maryland Company at present charges $18 a year for rental of 'phones in dwellings and $24 a year in business places. It is expected these prices will be still further cut. The Maryland Company has about five times as many subscribers in Hagerstown as the Chesapeake & Potomac Company.

Promoters are endeavoring to interest citizens of Mt. Clemens, Mich., in forming a company to establish a county telephone exchange similar to the one now successfully operated in Oakland County with headquarters at Pontiac. Members of the council have investigated the Pontiac plant with a view to getting information before granting a franchise in Mt. Clemens. Several prominent men of Macomb County are interested in the enterprise, and it is believed that a franchise will be granted at the meeting of the council. The promoters promise a fair rate and the company will be so formed that a consolidation cannot be made with other companies. The raising of rates by the Bell Company, immediately after its absorption of the New State Company was not realized by the patrons and it is thought that an independent county exchange will prove popular.

The Suburban Telephone Exchange, recently established at Wyoming, O., is now in operation. The new exchange has connections with Cincinnati and all the villages around that vicinity, especially in the Mill Creek Valley. Over 300 telephones have already been placed in the villages of St. Bernard, Elmwood Place, Carthage, Hartwell, Wyoming, Lockland and Reading.

The judiciary committee of the board of supervisors of San Francisco, Cal., lately reported in favor of accepting the option offered by the People's Mutual Telephone Company on its franchise, provided that no consideration be named. It is considered likely that the option will be accepted as soon as the city attorney renders his opinion. The new company is reported to have already secured 7,000 contracts for telephones, and a syndicate is ready to take all bonds as soon as issued.

For several months telephone subscribers at Stonington and Mystic, Conn., have complained of the poor service at night, owing to the wires of the local electric light company being strung on the telephone company's poles. The electric light current makes an annoying buzz which causes difficulty in conversation. It is stated that the telephone company has decided that the electric light wires must be removed. It was said at Stonington that the electric light people intend to make a change in the location of their wires, which, it is hoped, will obviate the present difficulty.

By a unanimous vote the governing committee of the Stock Exchange in this city adopted the plans for their new building as drawn by Supervising Architect George B. Post and previously submitted to the building committee. The work of erecting the structure will begin on or about May 1 next, when the present buildng will be razed, temporary quarters being taken at the Produce Exchange. The plans shown include the Broad street elevation. The building will be nine stories high on that street, and the general outlines will be after the Grecian style of architecture. The lower floor will be given over to telegraph, telephone and cable companies, messengers' rooms and the like.

Interests hostile to the Bell Telephone Company are organizing at Norfolk, Va., a local telephone company with a capital of $200,000, of which the interests referred to, it is declared, will take $100,000 if necessary. The purpose is also to operate long-distance lines between Norfolk, Washington, Richmond, Baltimore and other neighboring cities. R. Henry Jones, a Norfolk capitalist, is interested. The Norfolk "Dispatch" printed the full details of the proposed rival company, which recently increased its rate on local 'phones 100 per cent.

The Mutual Telephone Company of Erie, Pa., makes an announcement that its long-distance service, in connection with the Union Telephone & Telegraph Company, is now open so as to include Union City, Corry and Waterford, Pa. This will be of great benefit to the large number of subscribers, which the Mutual Company has in Erie, who do business with the people of the towns named above, and also for the residents of those places, who wish to communicate with users of Mutual 'phones in Erie. The Mutual line is being constantly extended in all directions, and is giving the public a most excellent service.

The telephone war in Morristown, Tenn., continues, and as a result citizens are enjoying the cheapest 'phone service in the history of the city. The Citizens' Telephone Cpmpany, composed of local capitalists, allows its subscribers the free use of its toll lines, while the East Tennessee or the Cumberland Telephone Company is giving residence service for 50 cents per month.

The Richmond, Va., and Peninsula telephone line is under construction and steady progress is being made. The work is already finished as far up as Lee Hall, some twenty miles from Newport News. This telephone line will follow the roads quite near to James River and will bring most of the plantations along the stream within talking distance of Richmond.

The Oxford County Telephone Company is setting poles for a line between Buckfield, East and West Sumner, and North and West Paris, Me. By this line connection can be made with the New England telephone line at West Paris and Buckfield. The line is about twenty-five miles in length, requiring 700 posts.

The Rome Home Telephone Company at Rome, N. Y., has filed in the office of the Secretary of State a certificate of extension of route from the boundary line between Oneida and Herkimer Counties, to the village of Herkimer, terminating in the exchange office of the Herkimer County Telephone Company in Herkimer, a distance of sixteen miles.

The Bell Telephone Company is to have a strong and forcible competition at Atlantic, Ia. The Musson Brothers of Des Moines are building a well-equipped telephone system at Atlantic, and by next spring they expect to have connections with every town in Cass County. They will be in shape to start business this week with 250 'phones.

The automatic telephone service at New Bedford, Mass., is working well and giving general satisfaction. In fact its popularity is growing daily and the promoters of the company are delighted with their apparent prosperity.

The New York & New Jersey Telephone Company is making quite an improvement at Northport, N. Y., by doing away with its many wires strung through the main streets, and placing them in cables of fifty wires each. When completed there will be but one coil, in place of a large number of single wires.

The new telephone line now being built through Black River Falls from Eau Claire to La Crosse, Wis., is being pushed along rapidly, and will be one of the finest lines in that part of the State. The poles through the city are put up 50 feet high, towering far above anything in the pole line.

The board of aldermen of Portland, Me., recently voted adversely on petitions of the Dirigo Telephone Company and the Eastern Telephone Company for right of way in that city. This action leaves the New England Telephone Company in control of the local field.

The Farmers & Merchants' Telephone Company of Warsaw, Coshocton County, O., lately filed a certificate of increase of capital stock from $5,000 to $15,000. The officers of the company are J. P. Darling, president, and S. C. Kirsner, secretary.

For two days last week the State of Vermont was shut off practically from the rest of the country. A snow-storm and high gale having blown down most all of the telegraph and telephone wires of the State.

The Hudson River Telephone Company has commenced an action against the city of Johnstown, N. Y., to secure a permanent injunction restraining the city from putting wires in a subway underground.

Work has been started on the erection of a telephone exchange at Bolton, Miss., which is on the line of the long-distance telephone, and is also being supplied with a local service.

A permit was recently issued to the Providence, R. I., Telephone Company for the erection of a new building on the corner of Broad and Corinth streets, which is to be used as a branch exchange.

The Harrison, O., council has granted a 20-year franchise to the Harrison Telephone & Exchange Company. The line will extend through Okeana, New London, Venice, New Baltimore, Miami, Elizabethtown and Cleves, O.

A telephone line is to be built from Durham, N. C., to Chapel Hill (the university of North Carolina) and work on it has begun, which is expected to be finished by the holidays.

The local telephone company at Fergus Falls, Minn., is putting in an underground conduit of twelve ducts. Two cables of 100 and 200 wires each will be put in.

The State Belt & Lehigh Telephone Companies will build a telephone line from Nazareth to Allentown, Pa. They will work in conjunction.

At the annual meeting of the stockholders of the Salem, S. D., Telephone Company, a 10 per cent. dividend was declared. The system was established last May.

The new telephone line between Cazenovia and Oneida by way of East Hamilton, N. Y., has been completed and is now in operation.

The local telephone exchange opened a short time ago at Red Lake Falls, Minn. The switchboard has 100 drops and they will all be used.

The Cumberland Telephone Company is asking for a franchise for the erection of a telephone system in Harriman, Tenn.

TELEPHONE INCORPORATIONS.

The Akron People's Telephone Company, Akron, O. Capital stock, $1,000.

The Saline County Telephone Company, Marshall, Mo. Capital stock, $25,000 to $35,000.

The Tyndall Telephone Company, Tyndall, S. D. Capital stock, $2,500. Incorporators: B. W. Burnett, J. D. Elliott, C. M. Stillwell and others.

The Bryan Telephone Company, Bryan, Tex.—to operate in Brazos, Burleson, Robertson, Madison and Leon Counties. Capital stock, $12,000. Incorporators: Spencer Ford, H. C. Robinson, F. E. Griseck, J. E. Butler and J. B. Mike.

The Sikeston Telephone Company, Sikeston, Mo.—to operate telephone lines. Capital stock, $12,000. Incorporators: G. M. Head, of Marianna; C. H. Sander, J. G. Stern, both of Forest City, Ark.; J. M. Chaney, R. M. Phillips, S. B. Hunter, all of Sikeston; J. B. Waker, of Benton.

The Huntingdon & Clearfield Telephone Company, Huntingdon, Pa.—to operate telephone lines. Capital stock, $1,000. Incorporators: C. M. Gage, of Huntingdon; B. F. Meyers, C. B. Stucker, both of Harrisburg; W. B. Barnard, of Philadelphia; W. H. Denlinger, of Patton.

GENERAL ELECTRICAL NEWS.

Lighting.

Brighton, Ia.—Brighton has decided to hold an election to decide whether or not the town will put in an electric light plant.

Bryan, O.—The city council is considering a change in the mechanical outfit at the electric light plant. New boilers must be substituted for the ones now in use.

Crowley, La.—This city has purchased and will enlarge the electric light plant of H. Widmer.

Dillon, S. C.—This city contemplates the installation of an electric light plant. Address S. S. Rozier.

Fairview, Mass.—The citizens are discussing the advisability of having more electric lights on their streets.

Franklin, La.—This city will issue $20,000 of bonds for adding power to its electric light plant.

Frenchtown, Pa.—The citizens of this village are making an effort to have electric lights for the streets and buildings of the place.

Gretna, Neb.—This town is discussing the question of erecting an electric light plant.

Jackson Springs, N. C.—The Jackson Springs Company, of which W. B. Hicks is secretary, wants information and prices on waterwheels and a 200-light dynamo.

Jasper, Fla.—B. E. Lennard, C. W. Smith, W. H. Greene and M. F. Home will establish an electric light plant.

John Day, Ore.—An electric company has been formed for the purpose of lighting this place and Canyon City. The capital stock is $10,000.

Jonesboro, Ga.—This city contemplates the erection of an electric light plant.

Juneau, Wis.—The citizens are considering the proposition to put in a $15,000 electric light plant.

Kearney, Neb.—The Kearney electric lighting plant was wrecked by an explosion a short time ago.

Kingston, Ont.—The civic light committee will recommend the council to establish a municipal electric light plant at a cost of $50,000 rather than arbitrate, and probably not buy the present plant owned by the Kingston Company.

Laurens, S. C.—The Laurens Furniture Manufacturing Company will install an electric light plant.

Ligonier, Ind.—The electric light plant at Hawesville was destroyed by fire recently. The plant will be rebuilt.

Los Angeles, Cal.—An application has been made to the city council for a franchise for the People's Lighting Company. It is proposed to furnish both electricity and gas.

Mystic, Ia.—The question of electric lights is again being agitated by the citizens of this town.

O'Neill, Neb.—The citizens of this place are agitating the question of erecting an electric lighting plant.

Oshkosh, Wis.—The time is near at hand, when the franchise of the Oshkosh Electric Light & Power Company expires; meanwhile a committee will investigate the question of municipal lighting.

Raubsville, Pa.—This town will be lighted by electricity by January 1.

Roswell, N. M.—Pete Wehner of the El Paso, Tex., Gas & Electric Light Company has obtained a franchise to establish and operate an electric light plant here.

Skaneateles, N. Y.—This village has voted to raise $1,000 to maintain the electric light plant and will have a municipal board of management.

Sparta, Tenn.—The Gainesboro Telephone Company of this city will receive bids for constructing a plant to have a capacity of 2,000 candle power and 500 candle power incandescent lights.

Sumas City, Wash.—There is an endeavor here to form a stock company among the leading business men for the purpose of putting in an electric plant to light the town.

Tipton, Ind.—Plans are being arranged for the establishing of a modern electric light plant here to be owned by the city.

Toccoa, Ga.—The Toccoa Falls Light & Power Company has been organized with E. P. Simpson president. It will erect an electric light plant.

Walla Walla, Wash.—An electric light franchise was granted to T. J. Kirk and others for the purpose of supplying the city with electric lights.

Waterloo, Ill.—Bids will be received until December 18 for machinery appliances and material and for the construction of a municipal electric light plant here. Geo. W. Ziebold, mayor.

Williamsburg, Va.—Several Richmond capitalists are considering a plan for erecting an electric light plant here.

Zionsville, Ind.—Zionsville will early in the new year construct an electric light plant.

Street Railways.

Beaumont, Tex.—The erection of a power plant to supply an electric railway is contemplated. Address I. D. Polk.

Bridgeport, Conn.—The sale of the Akron and Cuyahoga Falls Electric Railroad of Ohio to A. Radel of this city was consummated a short time ago. Mr. Radel assumed control of the property December 1. Over $100,000 will be spent in improvements, including an extension of the line.

Brooklyn, N. Y.—The Ridgwood power house of the Brooklyn Rapid Transit Company was destroyed by fire last week, with a loss to the company of about $150,000.

Kutztown, Pa.—The assistant superintendent of the United States railway mail service has inspected the Allentown-Kutztown Electric Railway, with a view to abolishing the star route between this place and Allentown, and having the service performed by the electric railway.

Larchmont, N. Y.—The Larchmont Railway Company has decided to substitute electric cars for the horse line now in operation.

Lincoln, Ill.—H. S. Beckemeyer of Mt. Pulaski has served notice that he will ask the board of supervisors for a franchise to build and equip an electric car line on the highway leading from here to Mt. Pulaski.

Middletown, Conn.—The Middletown Street Railway Company will ask the General Assembly next January for an amendment to its charter so that it can extend its trolley line to Meriden

Muskegon, Mich.—The Muskegon Street Railway Company will next spring relay its entire system with new rails at an estimated expense of $75,000.

Nevada, Mo.—Nevada contemplates having a new electric street railway in the near future.

Palmer, Mass.—There is beginning to be some talk of an electric railroad connection between here and West Warren.

Perth Amboy, N. J.—The board of freeholders of Middlesex County, has granted a franchise to the Raritan Traction Company of this place, for a trolley road along the Middlesex, New Brunswick and Perth Amboy turnpike from Metuchen to Perth Amboy.

Philadelphia, Pa.—It was recently announced that the Hudson River Traction Company, now operating a trolley line between the Fort Lee ferry and Hackensack, N. J., intends to extend its line west to Paterson, and soon through to this city.

Toledo, O.—Another electric railway is projected to run between Adrian, Mich., and this city. It will be built by the Toledo, Adrian & Jackson Railway Company.

Toronto, Can.—The corporation of this city desires to have an electric railway system constructed to run to and from the new St. Lawrence Market, Toronto, for a distance of 100 miles east, west and north therefrom, said railway system to have six or more main lines with branches and a total mileage for the present of 500 miles. E. A. Macdonald, mayor.

Wheeling, W. Va.—The electric street railway of this city will shortly consolidate with a capital of $6,000,000.

Worcester, Mass.—The Hampshire & Worcester Street Railway Company has petitioned the Legislature for commission to act as a common carrier of freight, baggage and United States mail.

Manufacturing.

Chicago, Ill.—Lewis Cook, William O. Chick and J. Albert Cook have lately formed a company, known as the Cook & Chick Company of this city, which will manufacture and deal in plumbing, heating and electrical supplies. The capital stock of the concern is $27,000.

Springfield, Mass.—The Stanley Electric Company has received the contract, amounting to about $100,000, from the Queens County Electric Company of New York for four generators of 1,200 horse power each. This concern has lately completed a 40-foot switchboard and two large generators for the Lehigh Power Company of Eastern Pennsylvania, worth about $40,000. It is now working on a switchboard for Englewood, N. J.

Company Matters.

New York City.—The board of directors of the Electric Vehicle Company held an important meeting last week at which it was announced that the company had absorbed the Riker Motor Vehicle Company of Elizabethport, N. J., and that a number of changes had been made in the list of officers and directors of the Electric Vehicle Company. George H. Day, of Hartford, Conn., was elected president.

Niles, O.—It is said that the Niles Electric Company will remodel its plant and put in a new engine and several new dynamos.

St. Louis, Mo.—By a recent request Mr. Wiggins introduced in the city council a bill to authorize the Imperial Electric Light, Heat & Power Company to construct, operate and maintain a heating and hot-water plant within the city limits, the franchise to expire on April 15, 1940.

St. Charles, Ill.—The supply factory of the Crown Electric Company here was burned recently. The building, valued at $17,000, with valuable machinery and stock, is a total loss.

Power and Transmission.

Boulder, Col.—A number of Denver capitalists are interested in an electrical plant scheme on the north fork of the St. Vrain Creek.

Silver City, Idaho.—Progress is rapid on the Swan Falls power plant of the Trade Dollar Mining Company of Owyhee County, and it will be rushed on to completion without delay.

Automobiles.

Cleveland, O.—The People's Automobile Company of this city has changed its name to the People's Automobile Manufacturing Company and its purposes so as to authorize it to make such machines.

Clyde, O.—The Messrs. Becker are now experimenting with a large automobile and will soon have one completed.

New York City.—The National Association of Automobile Manufacturers was held last week in this city. John Brisben Walker, in speaking of the association, said: "The association is not a trust. It does not intend to control the trade, but is simply an organization of men interested in the trade." The officers elected were as follows: S. T. Davis, Jr., president; J. H. Flagler, first vice-president; J. Wesley Allison, second-vice-president; C. J. Field, third vice-president; D. S. Walker, treasurer, and E. P. Wells, secretary.—The "Evening Telegram" of this city uses a pink electric automobile to distribute its papers. It is equipped with electric lights and bells throughout. The machine weighs 3,000 pounds, and is made to carry a load of 1,000 pounds.

Richland, O.—The Beardsley & Hubbs Manufacturing Company has been formed here to manufacture automobiles on a capital of $100,000. V. S. Beardsley, E. L. Sanderson, G. G. Hubbs, C. E. McBride, B. W. Willett, all of Mansfield, O, are interested in the firm.

Springfield, Mass.—The Skene American Automobile Company has been organized for the purpose of manufacturing motors of all kinds with $500,000 capital stock. The officers are: President, R. H. B. Warburton; treasurer, F. W. Robinson, both of this city.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The North Jersey Street Railway Company, which controls the street railway lines of Hudson County, N. J., has acquired the lines in Union County.

The Chicago Telephone Company has declared the regular quarterly dividend of 3 per cent., payable January 2. Books close December 26 and reopen January 3.

The Commercial Cable Company directors declared a regular quarterly dividend of 1¾ per cent. and a bonus of 1 per cent., payable January 2. Books close December 20 and reopen January 2.

The South Side Elevated Railway Company of Chicago has declared the regular quarterly dividend of ¾ per cent., payable December 31. Books close December 20 and reopen Janary 2.

It is reported in Minneapolis that a syndicate, composed of F. V. Green, A.W. Sewall, M. H. Elliott and others, is negotiating for the purchase of the Twin City Rapid Transit Company from Thomas Lowry.

The Brooklyn "Eagle" says there are strong financial interests in Manhattan willing to purchase control of Brooklyn Rapid Transit in the neighborhood of 50. It is understood strong efforts will be made during the next two or three weeks to force the price back to between 50 and 60.

An officer of the Chicago Union Traction Company is reported as saying: "November business was satisfactory, even though figures are not given out. Elevated competition has cut into our gains, but has not actually reached our profits. We will continue to pay a dividend as we have in the past."

The Syracuse Rapid Transit Railway Company reports for the quarter ended September 30, 1900: Gross earnings, $143,905, increased $21,271; net earnings, $63,413, increased $6,296; surplus after charges, $9,079, increased $2,321. The balance sheet shows cash on hand of $3,903 and a profit and loss surplus of $45,452.

Exports from the United States to Cuba, Porto Rico and the Philippine, Hawaiian and Samoan islands will aggregate more than $50,000,000 this year, against $41,000,000 in 1899, $19,000,000 in 1898 and $17,000,000 in 1897. This enormous growth is shared by each of the group of islands named, but is especially apparent in the case of Porto Rico.

The subscription to the 4 per cent. Third Avenue Railroad (New York) bonds which was opened last Friday morning at the office of Kuhn, Loeb & Co., was immediately closed, applications received being far in excess of the $10,000,000 bonds offered. The bankers state that bona fide investment subscriptions will alone be considered and that all speculative applications are to be declined.

The Electric Vehicle Company proposes to increase its capital stock by the issue of $1,000,000 preferred and $2,000,000 common, the proceeds to be used for payment of the shares of the Riker Motor Vehicle Company which has just been absorbed by the company. Robert A. Lloyd has resigned from the presidency of the Electric Vehicle Company and is succeeded by George H. Day, president of the Electric Storage Battery Company.

Lease of the properties of the Easton (Pa.) Consolidated Electric Company to the Lehigh Valley Traction Company was ratified at a special meeting of stockholders of the former company, held at their office in Camden Friday. The lease provides for the payment of an annual rental of $45,000, equivalent to 10 per cent. upon the amount paid in on the stock of the Easton Consolidated, which will be $15 a share after the final call has been made.

At a meeting in Boston on Monday the directors of the General Electric Company declared a dividend of 2 per cent., payable on January 15, 1901, to stock of record December 29, and an extra dividend of 1 per cent., payable on the same date. The extra dividend of 1 per cent. is to bring up the dividends to the 8 per cent. basis for the year. The previous dividends declared this year were 1½ per cent. for the quarter ending April, 1½ per cent. for that ending in July, and 2 per cent. for the October quarter.

The Boston "News Bureau" says: Great interest is manifested over the delay in probating the will of Marcus Daly, who, as president of the Amalgamated Copper Company, held at one time $15,000,000 of its total capital. It is declared in some quarters that the election of Mr. Scallon as president of the Anaconda, was necessitated by the Daly position in respect to Anaconda, and it is asked whether there may not be some Daly strings on the transfer of Anaconda stock to the Amalgamated, which are as potent to-day under Mr. Daly's will as when he was alive.

The following statement was made by a leading Philadelphia financier on Saturday: "The declaration of the Electric Storage dividend has given the stock a status it has never had before. Seeing the large earnings reported from year to year and no dividend paid had sort of made the public skeptical as to dividend prospects, but the present action has removed this. When it is found that the company can distribute out of its earnings $1,000,000 and more per annum, in the form of cash dividends to its stockholders, it is to be recognized that the Electric Storage Battery Company is an industrial proposition of considerable size, and that the talk of commercial success has not been all wind."

An interest in the $30,000,000 Telephone, Telegraph and Cable Company of America, says the negotiations are now going on for a combination of this company with other large telephone interests. He says that if the negotiations are consummated, he understands the Telephone, Telegraph & Cable Company stockholders will get a guarantee equal to 6 per cent of the amount paid in on the stock. It is said that if the combination is effected, the last assessment of $5 a share on the Telephone, Telegraph & Cable Company may be recalled, or in case the payments have been made, the amount of the call may be returned. Of the $30,000,000 capital only $13,765,000 has been issued, and $10 a share, or $2,753,000 has been paid in. The payment of current $5 call, or $1,376,500, will be used in extension of the business on the present lines, in case the arrangement now contemplated is carried out.

ELECTRICITY.

VOL. XIX. NEW YORK, DECEMBER 19, 1900. NO. 24.

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES, - . - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	2.00
FOREIGN COUNTRIES, - - - - - -	4.50
SINGLE COPIES, - - - - - -	10 cents

emit by Express, Money Order, Draft, Post Office Order or Registered Letter.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter

EDITORIAL NOTES.

Christmas—the Last of the Century.

Before the next issue of ELECTRICITY reaches its readers, the last Christmas Day of this century will have come and gone. The day—always one of merriment and good cheer—should this year be looked upon as one of thanksgiving by the whole country in general, and by the electrical fraternity in particular. Since the Christmas of 1899, the country has passed through the throes of a National election, and is assured of another four years of the same administrative policy, which, from a business standpoint, is to be desired, as a change of administration, whether for the better or the worse, invariably tends to upset business through uncertainty and apprehension of radical changes.

The electrical industry has much to be thankful for. In this country the demand during 1900 for electrical machinery and apparatus has been exceptionally brisk, while the principal manufacturers in the electrical line are reaching out into foreign countries for new markets, with what success may be inferred by an examination of the growing list of weekly exports.

It is to be hoped that the present unusually prosperous conditions will continue to prevail during the coming year, and that our friends, advertisers and readers, to whom we wish a very "Merry Christmas" and "Happy New Year," will one and all feel its influence.

* * *

Pipe Galleries.

In a large city galleries in which water mains, gas pipes and electric light wires may be placed, are much to be desired. Paris has its subways in which the innumerable network of mains (which literally fill the streets of New York) are placed, while London has a few miles of pipe galleries, with the prospect of many more in the near future.

The question as to whether pipe galleries should be built in conjunction with the underground rapid transit road in this city, has been discussed pro and con, and although the extra expense of such galleries will undoubtedly be great the demand for them is apparent to any one familiar with the underground topography of the city as it exists at present. It is no exaggeration to say that the principal thoroughfares, especially in the lower part of New York City, are so filled with underground structures, such as telephone conduits, electric light conduits, gas mains, etc., that in years to come it is hard to see how any more can be laid to meet the increased demand that must necessarily arise. In view of this fact pipe galleries, somewhat similar to those made use of to a limited extent in London, become a necessity. In the English metropolis, as explained in the issue of November 30 of the London "Electrician," the pipe galleries contain two miles of gas mains, about the same length of water mains, and five to six miles of electric light cable. These subways are built mostly with their crowns a short distance below the surface of the roadway or sidewalk and with their floor above the sewer. As a rule they are about 7 feet wide by 12 feet high and have vaulted roofs. The walls are of brick. Stone floors have been adopted and these are drained by shallow channels cut in the stone and leading to gratings placed every eight yards or so. These gratings cover bell traps, through which there is communication with the sewer beneath. In this way the subway is kept clean and dry. Immediately above each of these galleries, is a narrow ventilating shaft, terminating in a grating on the sidewalk or roadway. To avoid splashing and to collect the mud and water which comes down, large pans on tripods are placed beneath these roadway gratings, and these pans are emptied once a week. The heavy mains usually rest on suitable blocks along the floor of the subway, or are placed, in some instances one above the other, on specially constructed brackets. The telephone and telegraph wires are located in troughs running along the wall.

When it is desired to supply a consumer with either water, gas or electricity, the services are taken off through cast iron "service shoes," which are built into the walls of the cellars.

These subways are as a rule lighted by gas, although electric light is made use of in one instance. Precautions to avoid explosions from gas escapes are taken on opening the subways every morning. For the first inspection safety lamps only are used and if a gas leak is detected, immediate steps are taken to have it remedied.

Our contemporary adds that in this connection it is worthy of note that so far there has been no trouble from gas escapes, or from the bursting or leakage of water mains, and that it is this question and the question of ease of making service connections, which will weigh

Digitized by Google

most with the electrical engineer in deciding whether he shall favor the laying of electric light and power mains in subways in common with mains of other service, instead of in the street.

In a city such as New York the ideal subway system would be under the sidewalks, but this would mean the annexing of innumerable vaults throughout the business district, with the enormous expense which invariably accompanies such undertakings.

* * *

Another System for Purifying Sewage by Electricity. Another invention for purifying sewage by electricity has made its appearance, which is hailed by the daily papers as being something new and startling. The originator of this process is a resident of Newark, N. J., and in a recent issue of the Newark "Daily Advertiser" there appears a description of the apparatus and modus operandi of the process which is principally remarkable through its lack of technical accuracy and its indefiniteness. For instance, the article says:

"The sewage of a city can be turned into a receiving tank, where by screens the heavier parts are separated. The fluid then passes into a second tank which is filled with electrodes of manganese and dioxide with a little aluminum. These electrodes are set side by side, about three inches apart, and have openings in the side through which the sewage flows. When the tank is filled a force of about 110 volts of electricity is turned into the electrodes, and the process of devitalizing begins. All the impurities rise to the surface and form a thick scum. This separation of the noxious elements in the water is brought about, the inventor says, by the action of the electricity on the oxygen and hydrogen gases of which it is composed. The effect produced in the few minutes the current was turned on was certainly surprising. The water seemed to boil, first turning white as milk, and then a dingy brown. The scum formed quickly and soon assumed the consistency of putty. There is no sediment, all the impurities being driven to the surface. The water is then slowly drawn off and turned into the river, or can be stored in reservoirs for use in extinguishing fires or sprinkling the streets, thereby saving an enormous waste of clear spring water. The refuse is then removed from the tank and put into a 'digester,' from which it passes through a steam worm to a receiver, and becomes clear ammonia of much strength. This in turn is evaporated by steam, and becomes ammonium salts, which is worth to-day $56 a ton, with a limited supply. The coarser matter is converted in still a third receptacle into a fine odorless powder, which, it is claimed, is the finest fertilizer known. The inventor asserts that after the installation of a plant the works will pay for themselves, and an endless supply of hitherto wasted water will be at the disposal of the city using it. He has tested the apparatus with every known dye, with the same result. No noxious substance of any kind seems able to withstand the forces of disintegration produced by the electricity."

The New York "Herald," commenting on the subject, among other things says;

"If science has in this way mastered the purification of sewage, enabling cities to dispense with enormous and costly systems of sewers, there seems to be no reason why a similar process might not be employed to purify water. If organic impurities and disease microbes can be oxygenated by electricity, filtering plants and other methods of cleansing public water supplies will soon be back number contrivances."

As is well known the purification of sewage by electricity is by no means a new idea, Mr. Woolf having built a plant for this purpose at Brewsters, N. Y., as early as 1893. The Woolf process, which consisted in passing a current of about 700 amperes at a pressure of 5 volts between a platinum electrode and a zinc electrode immersed in salt water, which liquid was afterwards mixed with the sewage to be purified, has been tried at Danbury, Conn., at Riker's Island and other places. This electrical method of sterilizing sewage has proven fairly satisfactory, and unquestionably economical, but for several reasons it has not been extensively adopted. In the above item from the Newark "Advertiser," it is stated that the local inventor makes use of a current at a pressure of 110 volts, whereas in all the systems so far brought out, the voltage made use of—as in the case of the Woolf system—has been very low, usually not exceeding six volts. This statement, however, may simply be another one of the numerous errors in the item. The New York "Herald" wisely suggests that if sewage can be purified by a current of electricity, there is no reason why water could not be purified in a like manner. Possibly the writer meant this remark as a joke, for it is a well-known fact that electricity has indirectly been employed, to a limited extent, for purifying water for the past several years.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

General Greely, chief signal officer of the United States Army, has been informed that the signal corps telegraph lines in Porto Rico have been turned over to the control of the civil authorities of the island.

The first regular meeting of the Roentgen Society of the United States opened December 13 in the Grand Central Palace, New York. Besides the members in New York, about 200 delegates were present from other States. The meeting discussed the value of the X-ray as a therapeutic and pathological agent. In connection with the meeting was the most perfect exhibit yet placed before the public. It embraced static machinery of the most recent make, coils for generating and Crookes tubes of recent invention. Dr. Heber Robarts of St. Louis and Dr. J. Rudis-Jicinsky of Cedar Rapids were re-elected as president and secretary-treasurer, respectively. Other officers elected were: First vice-president, Dr. G. P. Girdwood of Montreal; second vice-president, Dr. Bender; assistant secretary, Dr. Price.

With a view to the establishment of a system of searchlights at the defensive works in New York harbor, the Chief of Engineers, Gen. Wilson, has submitted to Congress, through the Secretary of War, an estimate of the cost of such work, which he places at $150,000. The committee on appropriations will be asked to include this sum in the estimates for fortifications and other works of defense required for the use of the War Department for the service of the fiscal year ending June 30, 1902.

A stringent ordinance has been adopted in Oswego, N. Y., to prevent the careless stringing of electric wires which have caused great damage during the past year.

A dispatch from Manila states that the United States cattle ship Burnside this week will proceed to Damuguete, Island of Negros, to begin the laying of 600 miles of Government cable to connect Negros, Mindanao and Jolo. Negros and Cebu already have cable connection with Iloilo and Manila. The new line will extend from Damuguete to Oromaueta, Misamis, Iligata and Tagoloan, all on the north coast of Mindanao. A land line will connect Misamis and Tigum and the main portion of the cable will extend from Tigum to Zamboanga thence to Jolo. At present there is scarcely any telegraphic communication with Southeastern Luzon, owing to the persistent wire cutting. It is proposed eventually to connect that section and the larger islands adjacent by cable with Manila.

It appears to be settled that before the summer season arrives an automobile track will have been built at Newport, R. I., for the use of many racing and other machines which will be headquartered in that city during the summer.

A dispatch from Buenos Ayres, Argentina, states that a curious experiment was recently made there at the post office with Roentgen rays. About eighty parcels were addressed to importers of jewels. They were supposed to contain watches and jewels. The parcels were exposed to Roentgen rays for the purpose of ascertaining whether they contained jewelry. The importers protested against the opening of the parcels. The examination with the rays showed that all of the parcels contained valuable articles, such as gold watches and diamonds. This is regarded by the Government as an attempt at smuggling.

According to a cable dispatch from England, an inventor in that country claims to have perfected a method of utilizing air to supersede coal as a source of motive power. No details of the process are given.

Advices from London state that an invention which, if it may not go some way toward making lighthouses obsolete, is expected to be of much value in the prevention of shipwrecks was shown recently at Southend-on-Sea, before the marine authorities and navigators. They were all much struck by the possibilities of the invention. It is an automatic system of signaling, and will warn ships of their approach to dangerous rocks and coasts in all weathers, when a flashing light might not be seen and the boom of the foghorn might be unheard. A metallic conductor is fixed on an elevation ashore or a lightship or a reef or lighthouse. From this ætheric waves are transmitted over a zone which has a radius of seven miles. All vessels within that area fitted with receivers are warned of their proximity to danger. A bell rings and the receiving instrument records the name of the place which is being approached. The automatic part of the machine consists of steel bearings, with a number of teeth which pass over a Morse transmitter. No

Digitized by Google

operators are needed at all. The machine works automatically. In its elementary principle the system resembles Marconi's wireless telegraphy, but in detail the system is essentially different. A syndicate is already taking up the invention, which will shortly be put on the market.

During 1901 the German Government proposes to begin the construction of a telegraph line to connect Dar Es Salam, in German East Africa, with Lake Tanganyika. This line, which will eventually join the Cape to Cairo wire, is expected to cost $50,000.

The "Tribuna" (Rome, Italy) of November 29th states that, after repeated trials at Brescia with a furnace of 150 hp., for smelting iron by electricity, a furnace of 500 hp. has been installed for the production of iron, steel, and other metals direct from the ores. The process is the invention of Capt. Stassano, of Rome, and the experiments were conducted before a commission composed of Profs. Arno, of the Polytechnic of Milan, Del Lungo, of the Institute of Spezzia, and Engineer Siracusa, Director-General of the Italian Electric Company of Turin.

On the line between Gesundbrunnen and Lagerhof, Prussia, an extended series of trials has been made of electric locomotives of large tractive effort says the "Railway and Engineering Review." This line has a great number of difficulties in the form of grades, curves and crossings, but is located so that the current used is generated by water power. An alternating current of 12,000 volts is supplied by overhead wires and is reduced to 1-12th its tension at the motor. The trials on this branch line have proved so successful that it is expected to extend the operation of the line in this manner to include a greater district.

An electric railroad equipped down to the minutest detail, is one of the features of this year's playthings for boys. The owner may get electricity from an ordinary battery or may generate it from a dynamo driven by a turbine connected with a running water faucet in the house. The current is let into the rail by a tiny wire from the battery or dynamo and is picked up by a motor concealed in the boiler of the engine. He can run it at a speed of 150 or 200 feet a minute, or he can just make it crawl. There are passenger cars and freight cars, switches and signal towers, stations and sidetracks.

The official report of the finances of the Paris Exposition shows a loss of 2,000,000f. ($400,000). The total of expenditures is 116,500,000f. ($23,300,000). The receipts amounted to 114,500,000f. ($22,900,000). The loss is less than in any of the preceding expositions.

A remarkable natural phenomenon has developed in Brooklyn, at Rockaway avenue and Pacific street. One of the tall hollow iron trolley poles set in the earth, on the northeast corner of the street, has filled up with pure spring water, which is constantly spouting over the top like a geyser. The water has covered the ground in the vicinity and has frozen, making a regular skating pond.

The J. C. Risher Coal Company has begun the operation of its new electrical mining plants at Dravosburg, Hays and Shire Oaks, Pa. The dynamo hauls 50 mine cars on the incline at a time. The capacity of the Dravosburg mines is increased from 16,000 to 20,000 bushels a day and but half the force of miners is required now.

A new electric machine was put up at the postoffice in Poughkeepsie, N. Y., a short time ago. It is used for cancelling stamps and at the same time puts the post-mark on the letters. It is run by electricity and has a capacity of stamping and postmarking 35,000 letters an hour. The clerks find it a great convenience.

By means of an invention, in which the magnetic electric machine is utilized to develop an induced current of a high potentiality, capable of acting over a long distance or through strong resistance, there has been developed a system of electric signaling which, by dispensing with cumbersome and costly batteries, bids fair to revolutionize modern telegraphy, and materially lessen its cost. Another application of the principle of the invention adds to the ordinary fire alarm system safety, surety and economy. As heretofore developed, the current has not been available for long distances or against strong resistance, and hence not commercially practical except in a small way. L. G. Wooley, of Kenton, O., has perfected this application of the principle involved. Its operation depends upon the fact that a sudden half turn, ending abruptly, of an ordinary single coil magneto armature in the field of a powerful magnet, sends out upon the line connected with it a current impulse, which may be raised to an extremely high potential.

It is interesting to note points of superiority in the automobile that appear under adverse weather conditions. Recently, when the streets were covered with a slime, horses were falling down and electric cars were sliding in all directions regardless of rails and brakes; but the automobiles made their way through the discord and there is yet to be a report of any disadvantages experienced.

In Germany cork is said to have been used with success in isolating the vibrations and consequent noise caused by machines installed in or near dwelling-houses. A sheet made up of flat pieces of cork in mosaic fashion of corresponding size to the bed-plate of the machine, and held together by an iron frame, is laid under the machine. The source from which this information is gathered also alludes to the isolation, by means of cork, of each bolt or connection between the bed-plate of the engine and its foundation, but does not describe in what manner such isolation is effected. It is, of course, apparent that the mere sandwiching of a sheet of cork between the bed-plate of a machine and its foundation would not necessarily absorb troublesome vibrations, since each anchor bolt is a medium whereby the vibrations of the engine may be transmitted to its foundation, and hence to the floor and walls of the building unless effectively isolated from the same. How this effective isolation is obtained by the use of cork sheeting remains to be explained. For our part, says the London "Electrical Engineer," we should be more inclined to rely upon a specially-prepared foundation of extra area and solidarity and to a careful balancing of the reciprocating parts of the machine.

A complete overhead trolley system for the carrying of freight is to be introduced at the Stanley Works at New Britain, Conn., and several thousand feet of track will be laid to connect all of the departments. Flat cars will be used and the company will furnish its own motive power. It is expected that the trolley line will be in operation by January 1.

Large shipments of electrical machinery and material continue to be made to Italy where the demand for such articles is greater than in any other country in Southern Europe. The steamer Aller had on board upwards of $30,000 worth of electrical machinery on her last sailing for Genoa. The same vessel took for Milan, besides good sized shipments of electrical goods, extensive consignments of laundry machinery, typewriters and cash registers. Merchants engaged in the export trade with Italy claim that more than 75 per cent. of the American manufactured goods which enter that country go through German or British account. In traveling through Italy they assert one will not find a single representative of an American manufacturing firm. The European merchants have even samples of American goods from which they effect sales. The engineering concerns who make direct shipments from here to Italy, it is stated, secure their orders through the European branches at either London or Berlin. If direct representation were established the trade, according to well posted parties in the business, would increase very materially.

Among the many Christmas novelties now shown is an electric automobile. It is 10 inches long and 7½ inches high. The battery is placed under the seat, where it can be easily reached. It will furnish power to drive the vehicle from half an hour to an hour without recharging.

The introduction of electrical traction on the elevated railroads of Chicago resulted in a substantial increase in the number of passengers carried. The increase in 1900 thus far over the corresponding period of 1899 is said to have averaged 12 per cent. Electrical equipment of the Manhattan lines will enable them to carry more passengers than now, and it is confidently believed that it will also attract a larger patronage, but the percentage of increase, it is thought, will hardly be as large as it has been in Chicago, owing especially to the already enormous volume of traffic on the "L" lines in this city.

American Society of Mechanical Engineers.

At the meeting of the American Society of Mechanical Engineers, held in New York recently, the following officers were elected: President, Samuel T. Wellman, Cleveland, O.; vice-presidents, David Townsend, Philadelphia, Pa.; Jesse M. Smith, New York City; James M. Dodge; Philadelphia, Pa.; Stevenson Taylor, Hoboken, N. J.; Arthur M. Waitt, New York City; Ambrose Swasey, Cleveland, O.; managers, Edgar C. Felton, Harrisburg, Pa.; R. H. Soule, New York City; John A. Brashear, Allegheny, Pa.; A. H. Goodale, Waltham, Mass.; Francis H. Boyer, Somerville, Mass.; Alfred H. Raynal, Washington, D. C.; W. F. M. Goss, Lafayette, Ind.; De-Courcy May, Scranton; Pa.; D. S. Jacobus, Hoboken, N. J.; treasurer, William H. Wiley, New York City.

"Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 6.

A DAY WITH A WIREMAN.

We will record in this article a day's experience at wiring with a practical up-to-date wireman. He is not the man who comes to work every morning ten minutes late, armed with he familiar excuse of "trolley being blocked," and whose entire ambition appears to be to keep out of the way of the "boss" and can never see any farther ahead than the next pay day. This wireman is the "reliable" man who is sent out on all particular work, because the firm has confidence in him.

Our wireman's name is Tom Jones, and I was fortunate enough to be sent out as a "striker" with him. I will try to relate as closely as possible our experience during the day, dealing with the points that I think will be instructive to the practical worker.

"Jones, here are a couple of orders that I am particular about and I want you to take them."

Tom steps up to the desk and receives the orders which read as follows: Mrs. Brown, 11 North 27th street. Install push button at front door to ring bell in kitchen, also a "floor push" in dining room to ring buzzer in servants' entry. Mrs. Smith, 15 South 27th street. Bells out of order; repair.

We gathered up the necessary material, including wire, batteries, bells, sal-ammoniac, etc. Tom took his tool bag and some of the stock and I took the remainder and we started out. The material I had being rather inconvenient to carry I asked Tom to put the packages of sal-ammoniac in his tool bag. "No, sir. I would rather leave them in the shop and come back after them than carry that stuff in my tool bag. Don't ever put sal-ammoniac in the same bag with tools if you want good tools; it will rust them before you know it. Some of the other fellows do, but you ought to see their 'kit.' Why, I would no more think of trying to do a job with the tools that some of the fellows carry than I would of flying. There used to be a time when an electrician was equipped if he had a screwdriver, a pair of plyers and a jack-knife, but those days are past, and I tell you if you want to do good work you must have good tools to do it with. Wait until we get to work and I will show you the 'kit' I carry. This Mrs. Brown we are going to work for to-day is a little cranky, but I can get along with her all right. I'll give you a pointer. When you go to work for a party try and give them a favorable impression of yourself right at the start. Don't go up to the house as though you were ashamed of yourself and looking just as though you had been caught trying to steal the front gate. Try and make a good impression at the start, for then if you happen to get a little plaster on the carpet or something like that they are sure not to mind it, whereas if they do not like you from the first they'll be just nose'n around to catch something wrong and raise a fuss.

"Hello, this is No. 11. Good morning. Will you kindly inform Mrs. Brown that we are from Wire & Co. to do the electric work she ordered." The servant disappears and in a few moments Mrs. Brown enters. "Mrs. Brown, good morning. We hope we are not putting you to any inconvenience by coming so early." I was surprised at the way Tom talked, just as though he had called to a 5 o'clock tea or such like, but he assured me afterwards that it was a part of the trade, and to be a good, successful wireman it is about as necessary to be able to properly meet the people as it is to know how to do their work.

"John, show these men where they can leave their tools and wire." I took the tools and wire back to where John indicated while Mrs. Brown showed Tom where she wanted the bells and push buttons to be placed. After he was through we went down to the cellar and he said: "When you strike a new job don't be in a rush and get tools and wire scattered all over the floor before you know what you are going to do; just look around for a while and sort of get your 'bearings.' The first way you see to run the wires may not always be the best and it almost always pays to look around for a while."

While Tom was looking over the situation, figuring on the best means and ways for running his wires, I took occasion to look through his tool bag to see what tools a wireman should carry, for by this time my opinion of Tom's ability as a workman assured me that in all probability the "kit" he carried would be a complete outfit and an ideal one for a man engaged in that line of work. I kept a list, which was as follows: Two screwdrivers different sizes, one pair long nose plyers, one pair diagonal cutting plyers, one pair flat nose 5 inch plyers, one small keyhole saw, one 20-inch cross-cut saw, a ratchet brace with about a half dozen long bits of various sizes, a long flat steel wire, which I afterwards heard Tom call a "fish-wire," a stout jack-knife, one small alcohol soldering torch with soldering iron, two wood chisels, one medium sized hammer, a bottle of shellac, one pair of 6-inch gas plyers, one ½-inch star brick drill, one long brad awl, a two-foot rule and a telephone receiver. Beside this collection of tools there were a couple of small bags containing assorted screws, nails, insulating tape, solder, a ball of stout twine, etc.

Before we started to work Tom volunteered the following information, which is a good rule for guiding wiremen in work of this class: "Run a wire from one pole of the battery, connecting it to one side of every push button, and a wire from the other pole of the battery to one side of each bell or buzzer, then connect a direct wire from each push button to the corresponding bell or buzzer to be rang by that individual button."

During the installation of the bells for Mrs. Brown I noticed the following points relative to the work which I think it will be well to remember. In putting up vibrating bells always place them with the gong pointing downward, for then there is not liable to be an accumulation of dust settle in them through the opening in the shell where the vibrator works.

Where push buttons are placed outside, exposed to the weather put a coating of shellac on the surface to be covered by the button and also surrounding the edge of it, when mounted, to prevent dampness attacking the wires and causing trouble.

Always do concealed wiring where possible by "fishing" through the partitions to the cellar. This is done by making a fine hole through the plaster where the bell or button is to be placed; then drop a string, with a lead weight attached down the space inside, and allow it to tap on the ceiling of the basement; by this means the exact spot can nearly always be found, then by boring up through the cord may be secured, to which attach the wires, pulling them up by it.

Never place the batteries in a warm place or up between the "sleepers". Try and secure a cool spot where they will be convenient of access. After the batteries are set up always wipe the tops of them perfectly dry.

Keep away from damp places with the wires and do not fasten them up with double pointed tacks, but instead use a more modern method, such as small specially constructed wooden cleats. When open work has to be done in a room a very fine wood moulding corresponding to the interior finish is advisable.

Always tape and shellac wires where they go through holes in plaster.

Never start to bore a hole in floors or walls without first investigating the conditions where you expect to come out at on the other side.

When we had completed and thoroughly tested the work at Mrs. Brown's we went to Mrs. Smith's to repair the bells. She informed us that the batteries had been fixed up just a few weeks previous, but when we looked at them they were entirely worked out. A great many wiremen would just have renewed the batteries and let it go at that, but Tom surmised at once that there must be a leak somewhere to cause them to run out so soon. so after renewing the cells he took his telephone receiver, connecting it in series with the circuit, and tapping one of the contacts discovered that there was current going to waste somewhere. The old method was by "tasting" for a leak in the circuit, but Tom had abandoned that for the more modern and a great deal more accurate means of using a telephone receiver.

We soon discovered the cause of the trouble, which existed in a damp point where both wires were under a double pointed tack. After remedying this trouble and testing again to make sure that no further trouble existed we packed up our tools and returned to the shop, satisfied with our day's work.

While reflecting over the day's experience I came to the conclusion that if all wiremen would use the same caution and good judgment that our friend Tom did the trade would be benefited to a great extent and we would not so often see the card on the front door which reads—

"Bells out of order. Please knock."

Article No. 7 will be entitled "Instruments for Electrical Measurements."

Rapid Transit in Constantinople.

Several enterprising Turkish capitalists are considering the feasibility of installing a system of electric street cars in the city of Constantinople. If a franchise can be secured such as the companies operating in American cities enjoy it is almost certain that the scheme will be carried out. M. Iran Cidzebcarn, a prominent miller of Constantinople, who has lately been in St. Paul, Minn., says he believes there is a great need for rapid transit in Contantinople and that soon modern conveniences will be in vogue there.

THE TELEGRAPHONE—A MAGNETIC SPEECH RECORDER.*

BY VALDEMAR POULSEN.

Following is a description of the principles and the arrangement of my invention which I have called the telegraphone. A steel wire (piano wire) AB, about 1.5 m., 5 feet long and 0.5 mm., one-fiftieth inch in diameter is stretched on a board, Fig. 1. Along it can slide the electromagnet E, which embraces it with one of the poles, Fig. 2. The core of the electromagnet is a piece of soft iron wire about 8 mm. (one-third inch) long and 0.75 mm. (three one-hundredth inch) in diameter, and the electromagnet itself is in series with a battery and a microphone, or is connected to a transformer in the microphone circuit. At the beginning of an experiment the wire should be completely unmagnetized.

If, while the electromagnet is sliding along the wire with a velocity of about 1 m. per second, the microphone is spoken into, the current fluctuations produced register themselves by means of the electromagnet on the steel wire. If now the electromagnet is connected up with a telephone and made to travel over the wire again, the telephone repeats what was spoken into the microphone. Thus, owing to the great coercive strength of steel, there has been impressed on the wire in undulations, so to speak, of magnetization, a kind of writing which is permanent, and faithfully

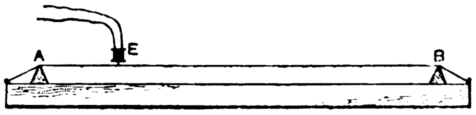

FIG. 1.

records the articulations of the voice. When E is put, now, in direct connection with a moderately strong battery and is made to pass once more over the wire the magnetic writing is obliterated under the influence of the constant magnetizing force, which is great compared with the intensity of the writing magnetic forces.

The wire AB is too short to contain many words. In order to obtain a larger capacity a very long piano wire is wound very firmly round a drum having a fine spiral groove on its surface, and the piano wire follows this spiral groove. Parallel with the axis of the drum there is a rod upon which a kind of sleeve can slide. The electromagnet is fastened to this sleeve. When the apparatus is in operation, the electromagnet embraces with one of its poles, or with both, the steel wire, Fig. 3, and during the rotation this steel wire itself pushes the electromagnet and the sleeve along the rod. It is very easy to handle a drum of this kind, and the whole arrangement is very convenient for experiments. Of course, it must be borne in mind that in the various telephonic and telegraphic applications of the telegraphonic principle there are certain conditions which must be fulfilled. The nature, dimensions, and cost of the writing basis, and the velocity, the construction of the electromagnet and the magnitude of the current must all be considered. Without going into details here I only beg to direct the attention upon some essential points concerning the three proceedings, viz., the inscription, the reproduction, and the obliteration.

Most frequently the inscription is effected by means of a polarized electromagnet. but the polarization and the degree of the polarization must not be arbitrary. Let, for instance, the electromagnet, by means of which the writing is to be performed, obliterate a prior magnetic record and also simultaneously magnetize the writing basis. Then during the inscription the electromagnet is given the polarization opposed to that which it had during the obliteration. In this way a lively movement of the molecular magnets is obtained at the very moment of forming the writing. The susceptibility seems to increase very much in that magnetic status nascendi, and every shade of

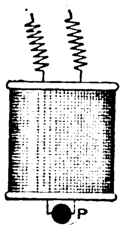

FIG. 2.

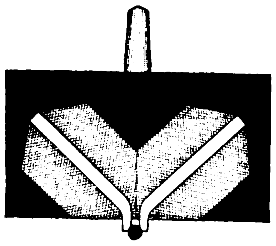

FIG. 3.

the writing becomes extremely perceptible. Ordinarily the polarization of the writing magnet is only a very small fraction of that of the obliterating one. The nearer its polarization approaches to the neutralization of that of the writing basis, however, the feebler may be, of course, the polarization of the obliterating magnet. The coercive force determines the degree of polarization which exactly neutralizes the magnetization of the writing basis. It is found that the writing is somewhat weak when the polarization of the electromagnet during the process of inscription is just equal to that used in the preceding obliteration. In order to polarize the electromagnet a constant current or a permanent magnet may be used.

If the positive and negative curves of an alternating current differ, their faculty of producing the writing may equally differ. This explains the peculiarity that the direction of the primary current with a certain polarization of the writing basis may sometimes influence the writing which, in the secondary

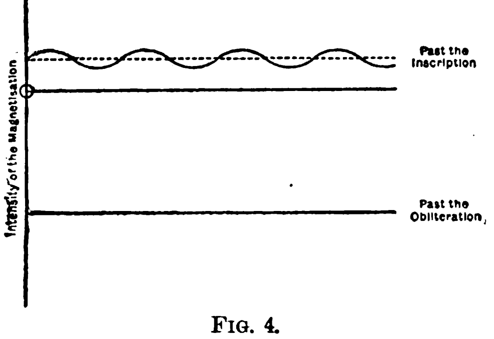

FIG. 4.

circuit, is performed by an unpolarized electromagnet. This is owing to the lack of uniformity in the manner in which the resistance of the microphone is increasing and diminishing. The inequality here spoken of is perhaps the more considerable the more the mobility of the carbon granules is considerable.

It seems that a speech (or a song) inscribed on the wire may be reproduced indefinitely without any perceptible diminution in clearness, the tone of the voice remaining perfectly distinct. Even when the apparatus is as primitive as that of Fig. 1, the reproduced voice is distinguished by the highest clearness and purity, and free from disturbing accompanying noises. The telegraphones of more recent date are able to reproduce with the greatest exactitude not only words spoken or sung into the microphone, but also whispers and even the feeble sounds of respiration.

The writing is completely obliterated by passage through a magnetic field of sufficient strength. Ordinarily it is sufficient to let the writing basis pass the writing magnet or another small electromagnet energized by a current from two or three cells. If a speech, however, be inscribed by means of an unpolarized magnet on a writing basis already written upon there results, as a rule, not an obliteration, but an interference.

Besides common piano wires, steel ribbons and nickel wires have been used as writing bases. The dimensions of the steel ribbons were 3 mm. × 0.105 mm. (one ninth-inch × one-fiftieth inch). The steel ribbon passes from a roll to a second receiving roll, where the layers of the ribbon may cover each other without the writing being destroyed. As to this last point, it has been proved by experience that the magnetism does traverse the ribbon, though as a rule, there is sufficient air space between consecutive layers to afford nearly complete protection. With a speed of about 1 m. (3 feet) per second, 0.154 liter, one-fiftieth cubic foot of steel is needed for a speech lasting an hour. Instead of ribbon, a fine piano wire unrolling from one place to another may be used. In some cases nickel may with perfectly good effect be used as a

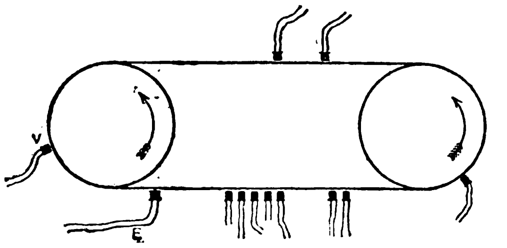

FIG. 5.

writing basis, which fact is in accordance with the known properties of this metal as regards permanence for weak magnetizations, and demonstrated by A. Abt. The great dependence on mechanical influences which is characteristic of the magnetic state of nickel demands, however, careful handling of the nickel wire. It is not likely that the common steel used hitherto is exactly the most suitable for telegraphonic purposes; most probably other and better kinds are to be found.

I have no intention of speaking of all the various specifically phonographic applications of the telegraphonic principle, nor of the constructive differences in connection with such applications. Nevertheless, I think that the following arrangement ought to be sketched: A long steel ribbon is stretched between two rolls which can rotate at a rather considerable speed. The ribbon passes a series of electromagnets of a speed regulated according to the circumstances. The electromagnet E inscribes words, music, etc.; the other electromagnets—"the reading magnets"—reproduce the communications in the telephone of each hearer; and, finally, the obliterating magnet, V, equalizes the magnetic variations of the ribbon ("telephonic newspaper," Fig. 5.) As using does not weaken the writing, we are able to intercalate any number of reading magnets.

Again, it is possible to use the telegraphone to increase the telephonic current (telephonic relay). The engineer, E. S. Hagemann, has proposed an arrangement which, theoretically at

*From the "Electrician," London.

Digitized by Google

east, is very simple, and which I here describe. A drum is provided with a series of circular steel rings having their centers in the axis of the drum, their planes perpendicular to the axis. As the drum rotates, whatever is spoken into the microphone is inscribed on the first ring by means of a writing magnet. By means of a series of reading magnets placed on the first ring, the words are transmitted to the other rings, which synchronically carry their equally formed writings past their reading

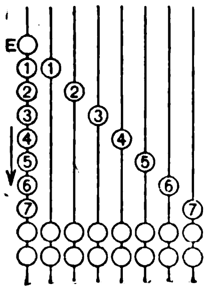

Fig. 6.

magnets, duly connected together, and afterwards past obliterating magnets (Fig. 6).

An elegant method of compensation has been invented by the engineer, P. O. Pedersen, and allows several speeches to be intermingled, is that they can afterwards be reproduced separately. As it is not feasible to describe this method satisfactorily in a few words, I shall not speak further of it here. Later, perhaps, Mr. Pedersen himself will make a communication about it.

In my endeavors to develop the telegraphone I have received the greatest assistance—first from Mr. P. O. Pedersen, and also from Mr. E. S. Hagemann. I owe them both my best thanks. I have, besides, to thank the Institution and experts abroad, as well as those of my own country, for the interest they have shown in the telegraphone.

POWER AND LIGHT FOR THE MACHINE SHOP AND FOUNDRY.*

BY FORREST R. JONES,
Worcester, Mass.

Although there have been several papers read before this Society upon electric power transmission for the machine shop and foundry, and the discussions thereon have been extensive and interesting, the question is of such growing importance that it is believed that more attention can be very advantageously given to it. Some of the papers and discussions have taken up lighting in connection with power transmission, but this has not generally been the case. The two are frequently so closely connected, however, that one often cannot be fully studied without the other. The writer has recently had occasion to investigate the plants of two concerns with regard to electric power transmission and light. In one of these, the floor space over which light and power are required is about seven acres; in the other, about four acres. The arrangement of the floor space is radically different in the two cases. In the first, there are several buildings entirely separate and at some distance from each other, and the floor space is nearly all upon the first floor, there being a small amount upon the second floor, and next to nothing on the third floor. In the second, the floor space is almost all in an L-shaped building, partly of four stories and partly of three, and, in addition to this, a small two-story structure setting close to the other building within the inner angle of the L.

The output of each establishment is in a way similar, both producing iron machinery chiefly. In the smaller establishment, the product is much lighter in weight than in the larger. The operating machinery in the two plants is quite similar, the lighter machinery is about the same in each, but the larger has a considerable amount of heavy machinery which has no counterpart in the smaller. Both plants were examined to see what requirements would have to be fulfilled by an electric system, or systems, for power transmission and lighting. The first examination was made with a view to determining whether one or more kinds of current (of the direct, single-phase alternating or polyphase class) would be desirable. In both cases the same conclusion was reached, namely, that the most feasible way to meet all requirements would be to adopt either one or more systems of electric circuits, the current to be of the same kind in each system if more than one were used, such that any electrical apparatus to be used in the plant, when placed in the location fixed for it, could be individually and conveniently attached to the electric circuit at a near point and operated by current therefrom in a manner suitable to the requirements of the service the apparatus was designed to perform and the limitations of the service for the particular locality, the latter to allow for taking into account the fact that, at some places, a motor must run with a speed varying but slightly from uniformity, while at other places, and for other services, considerable variation of speed might not be objectionable; also, that while the electric light, might in some places, be required to operate with a uniform brilliancy and absence of fluctuation, as in an office or drafting room, there might be other places to illuminate, such as the foundry, casting-cleaning room, or an emery wheel, where a very considerable variation in its brilliancy would not impair its usefulness.

The selection of a single system from which all apparatus might be operated was based upon the conviction that, for machine shop and factory purposes, it is exceedingly desirable to be able to interchange similar apparatus and to place any piece of apparatus anywhere upon the system, thus obtaining the maximum flexibility and greatest facility for operating portable machine tools at any point, and also to allow for alterations and extensions of the works. The study of the requirements of every form of apparatus that might be brought into use and demand current from the system was naturally necessary in order to decide whether direct current, single-phase alternating, or polyphase, should be used.

The oldest of machine tools, the lathe, was taken up first, and since in both establishments it was deemed advisable to have some lathes driven individually by variable speed motors, and that the variation of speed should cover, by small steps, a considerable range, the only thing that seemed satisfactory for this purpose in the present state of speed regulation for different types of electric machinery was the direct current. And, in order that the range of speed variation might be as great as possible, the multiple voltage system appeared to be advisable, even though the speed regulations were to be made, for a given supply circuit voltage, by rheostatic control of the current in the magnet coils of the motor.

Other machines of a nature in a way similar to the lathe, so far as their driving is concerned, among which may be included the boring mill, drill press, shaper, slotter, gear cutter and screw machine, can be operated satisfactorily under conditions of speed variation similar to those which answer for the lathe.

The planer, whose reciprocating motion requires the reversal of nearly every part of its machinery, presents a problem which is not yet satisfactorily solved for electric driving by a direct-connected motor. The nearest solution that has been reached is to drive its countershaft in one direction continuously, just as it might be driven from a line shaft, and effect the reversals of the machine in the ordinary method common to mechanical driving. The ability to secure different cutting with maximum return speeds for machines of this type is unquestionably desirable when working upon different kinds of materials or for taking heavy and light cuts. Different speeds can be obtained readily with many types of direct-current motors by rheostatic control of the field magnet current, and, therefore, this feature needs no further attention than already given the lathe.

Nearly all electric hoists and cranes are now operated by constant-pressure, direct-current motors. They seem to be at least as satisfactory as those driven by any other type of current.

Constant-potential, direct-current arc lamps have long shown themselves efficient, durable, and otherwise satisfactory. They can be operated individually and economically at any pressure between 100 and 125 volts, even though the pressure fluctuates considerably. (It is not intended that these are the limiting pressures of satisfactory service.) The lamp is, of course, more economical at its rated pressure without any of its rheostatic resistance in circuit. Incandescent lamps have long been operated at from 100 to 110 volts with perfect satisfaction.

Motors for electric cranes and for general power purposes about the machine shop can be operated satisfactorily at any of the ordinary pressures for running motors, but it was not thought advisable, especially in connection with conditions to be met in operating other apparatus, to give them a pressure greater than from 220 to 250 volts. The higher the voltage, within practical limits, the greater the economy of wire in the electrical circuit, of course. But, even leaving the requirements for other apparatus out of consideration, voltage as high as 500 is not desirable for the machine shop and foundry, for there is always a considerable degree of probability that employes will receive shocks by coming in contact with the wires or machinery. The writer's experience has given him sufficient respect for a 500 volt circuit to make him wish to keep others away from it.

On the whole, it was, therefore, concluded that 220 volts for the majority of motors, and 110 volts for arc and incandescent lamps, would be the most suitable. These voltages can be obtained, as is well known, by the three-wire system which has been so long in use.

In order to obtain information as to the amount of power required for driving different parts of the plant, numerous tests were made upon individual machines, groups of machines, sections of line shafting, cranes and elevators. Although so much data have already been published showing the power required to drive

* Abstract of paper read at the New York meeting, December 4-7, 1900, of the American Society of Mechanical Engineers.

Digitized by Google

machine tools for iron working and wood working, it is believed that there are some points of sufficient value among that obtained in these tests to entitle them to attention. The data given below are of a nature not generally found in the reports that have been made upon electric driving, but present some rather unusual cases.

The power required to drive a couple of lathes, one of 48 inch and the other 36 inch swing was taken when both were polishing hollow cylindrical columns, one 10 inches in diameter, and the other 12 inches. In both cases the polishing laps gripped the work so tightly as to keep the driving belt of each lathe on the point of slipping. The speed was as high as could be safely used for machines of this size. To drive the two lathes together under these conditions, something over seven mechanical horse-power delivered by the motor to the belt running from its pulley was required. It can be seen that this is considerably more than is required for a lathe performing any of the operations common to machine construction in the ordinary shop. It may not equal the amount of power necessary for taking heavy cuts upon large steel shafts, heavy gun tubes and jackets, etc. It does represent the power, however, which must be used as a basis to determine the size of a motor to drive a lathe which must do such work as demanded for these two. If a number of lathes for this class of work are to be grouped together, and there is a possibility, which is very probable, that several of them may have polishing under way at the same time, and therefore demand a maximum amount of power, the motor for driving them as a group must naturally have a capacity equal to the combined maximum demands of all of them, due allowance being made for its ability to stand overloading for a short period of time.

Although it is well known that the power required to drive a metal-working planer is generally greater on the return stroke than for the forward, or cutting stroke, and that, at the time of reversal, the power demanded is exceedingly greater than at any other time, the following data may not be out of place.

Two planers, one with 22 foot table and 120 inches between housings, and the other with 25 foot table and 72 inches between housings, were both driven by one motor belted to a jackshaft, which in turn drove the two countershafts of the planers. The following data were obtained:

120-INCH PLANER WITH 22-FOOT TABLE AND 72-INCH PLANER WITH 25-FOOT TABLE.

(Both machines driven by one motor. Jackshaft running in all cases. Pressure 230 volts.)

Amperes.	
20	One countershaft.
60	Average for 120-inch planer on cutting stroke, light cut, and one countershaft.
55	120 inch planer reversing from return to cutting stroke.
110	120 inch planer reversing from cutting to return stroke.
27	Both countershafts.
240 } 250 }	Both planers reversing from cutting to return stroke.

Both machines were working upon rather heavy castings and taking comparatively light cuts at short strokes over bosses and parts of the castings where other members of the machines were to be attached. The power, therefore, is approximately that which would be required to drive the machines without taking any cut, but carrying loads upon their tables. It may be noticed that the amount of power for reversing the 120-inch planer was about 1.8 times that for its average running at time when not reversing. When it happened that both machines reversed at the same time from the forward, or cutting, to the back, or return, stroke, the power required ran up to a very great amount, more than 60 mechanical horsepowers. This amount of power was not indicated by the instantaneous extreme throw of the ammeter needle, but was the reading at which the ammeter stood steadily for some seconds, a period long enough to make the demand distinctly felt by the engine and generator.

A planer with a 40-foot table and 74 inches between housings gave the following data. The great power required for reversing from the cutting to the return stroke again stands out:

74-INCH PLANER WITH 40-FOOT TABLE.

Cutting speed, 20 feet per minute; two tools operating on cast iron; cut on each, ½ inch deep, ⅛ inch feed. Pressure 234 volts.

Amperes.	
22	Countershafting only.
50	Considerable portion of the time while cutting.
60	For some moments while cutting.
35	Middle of return stroke.
90	Reversing from return to cutting stroke.
120	Reversing from cutting to return stroke.

Of the twenty odd traveling cranes in one establishment, ten were tested for the power required to drive them. Of these ten, some were driven electrically and some mechanically. The majority of the electrical cranes were of the ordinary types designed for electric driving. One was a remodeled crane which had originally been driven mechanically by a square shaft running alongside the building parallel to the track. Some of the mechanically driven cranes were furnished power by a square shaft alongside the building and parallel to the track, and others by a flying rope running alongside the track. Obviously, in providing for the power to drive a crane it is necessary to know the maximum amount of power that it may demand for a period of time great enough to make the demand appreciably felt by the generating plant. In this respect the following data, obtained from three electric traveling cranes of 30 tons capacity each, all traversing the same track above the foundry floor, show how great may be the demand, for an appreciable period of time, by some one of the cranes, and, with perfect possibility, by all of them at the same instant.

Each of the 30 ton cranes was equipped with four motors, 25 horse-power for bridge travel; 8 horse-power for trolley travel, 25 horse-power for the main hoist, and 16 horse-power for the auxiliary hoist.

30-TON ELECTRIC TRAVELING CRANE NO. 1.

(Pressure 240 volts when crane was taking no current.)

Amperes.	
125	Bridge starting, no load.
50	Bridge traveling uniformly, 350 feet per minute, no load.
33 to 40	Lowering, no load.
105	Starting to hoist, no load.
36	Hoisting uniformly, no load.
145	Bridge starting, 20-ton load.
50	Bridge moving uniformly, 240 feet per minute, 20-ton load.
95	Hoisting 20-tons uniformly at 10 feet per minute.
310 } 200 } 150 }	General manœuvring, 20-ton load.

30-TON ELECTRIC TRAVELING CRANE NO. 2.

(Pressure 240 volts.)

Amperes.	
110	Bridge starting, no load.
65	Bridge traveling uniformly, 450 feet per minute, no load.
15	Trolley starting, no load.
13	Trolley moving uniformly, no load.
36 to 50	Lowering, no load.
130 to 150	General manœuvring, no load.
90	Bridge starting, 20-ton load.
50	Bridge traveling uniformly, 20-ton load.
145	Hoisting, rapid start, 20-ton load.
115	Starting to hoist, reading for 3 seconds, 20-ton load.
95	Hoisting 20 tons uniformly at 10 feet per minute.
260	Bridge and trolley starting, reading for a few seconds, 20-ton load.

30-TON ELECTRIC TRAVELING CRANE NO. 3.

(Pressure 240 volts.)

Amperes.	
90	Bridge starting, no load.
50	Bridge traveling uniformly, 535 feet per minute, no load.
38	Lowering uniformly, no load.
40 to 45	Hoisting uniformly, no load.
150	Bridge and trolley starting, 20-ton load.
30	Trolley at uniform speed, 20-ton load.
34	Hoisting uniformly at 11 feet per minute, 20 ton load.
240	Bridge and trolley manœuvring, reading for 3 seconds, 20 ton load.
320 } 250 } 200 } 230 } 180 }	General manœuvring, 20-ton load.

It can be seen, by examining the data obtained from these 30 ton cranes, that when all the motions on one were in operation simultaneously, and when two or more of the movements were started at about the same instant, the demand made for power during this general manœuvring was very great indeed. The readings given for such general manœuvring for two of the cranes when carrying a load of 20 tons each, the reading running as high as 320 amperes in one case and 310 in the other, represent demands for current during periods of from five to ten seconds' duration, as shown by the steady reading of the needle of a dead beat ammeter. It not unfrequently happens that such a condition comes about in everyday practice. That two or more of these cranes did, when in regular service, make very heavy demands for current at the same instant, was clearly shown by watching the ammeter at the switchboard of the generator supplying current to the three cranes only. Although this generator had sufficient capacity to operate several 30-ton cranes under what might be called average load, and the magnetic circuit breaker for the generator was set considerably above the steady-load capacity of the generator, it was not an unfrequent occurrence for the circuit breaker to open up the circuit on account of the great momentary demands made for power by the cranes.

Tests upon a 15 ton electric crane, two 5 ton electric cranes, a 15 ton flying-rope crane, a 15 ton square-shaft crane, and a 15 ton square-shaft crane remodeled to be driven direct by an electric motor, all showed similar heavy momentary demands for current under general manœuvring.

By examination of the data given above, it may be seen that the constantly recurring and great momentary demands for power made by cranes and hoists would necessarily affect the pressure in the wires carrying current to them from the switchboard in the power-house.

Digitized by Google

Hence the circuit feeding the crane would not be suitable for also furnishing current to motors which require to be run at even a fairly constant speed, or even hardly for incandescent lights in places where a steady illumination is not essential. It would be difficult to find constant voltage arc lights that would operate with even a fair degree of satisfaction at the points of greatest variation of pressure in the circuit. It, therefore, becomes necessary to have what might be called a "crane circuit" for at least the majority of the larger cranes in an establishment of the proportions of those mentioned earlier in this paper.

The incandescent lights for use in offices, drafting rooms, and possibly some parts of the shop itself, as the tool room, and where the small and more accurate parts are manufactured, must have a pressure in the circuit leading to them which, at least, does not fluctuate rapidly, even though it may be allowable for it to vary slowly to a slight extent. A "lighting circuit," primarily intended for incandescent lighting, therefore, also becomes a necessity.

Such machinery as lathes, drill presses, shapers, milling machines, slotters and gear cutters do not ordinarily need to be driven at a speed that is even very uniform. Variation of speed on each side of the normal is allowable to a considerable extent in many cases, provided the variation is not a jerky one, such as often comes on line shafting used to drive heavy planers. A third circuit, primarily intended for driving machinery of this class, needs to be installed. This may be conveniently referred to as a "machine-tool circuit."

Whether an iron-working planer may be placed upon the machine-tool circuit depends largely upon the size of the planer. The heavier machines, on account of the great momentary demands they frequently make for power would be apt to produce sudden and considerable variations of pressure in the machine-tool circuit. Better general operation of the entire plant can be obtained by placing them on the crane circuit. The smaller planers can safely be placed upon the machine-tool circuit, thus obtaining more uniform motor speed for driving them, while not materially affecting the pressure in the latter circuit.

The pressure on the machine-tool circuit would remain constant enough to operate constant-pressure arc lamps with perfect satisfaction. Such lamps, therefore, may be placed anywhere upon either the machine-tool circuit or the lighting circuit, and possibly upon some parts of the crane circuit where the fluctuation of pressure is a minimum for that circuit. Incandescent lights can, of course, be placed upon any of the circuits. The pressure in the machine-tool circuit should be sufficiently constant to insure a brilliancy uniform enough for many places in which an incandescent lamp is put.

Important New Developments in Electric Automobile Building.

Public announcement has just been made of the perfectment of a light, comparatively inexpensive storage battery of unusually high efficiency, which is quite likely to cause a revolution in the methods of electric automobile construction. Heretofore the great stumbling block in the way of builders of electric wheels has been the cumbersomeness and great weight of equipment which the batteries heretofore used have necessitated. Now comes a Cleveland, O., electrician of wide reputation on two continents, with a perfected electric storage battery, upon which he has experimented quietly for five years and which is said to be made from entirely new and wonderful chemical combinations—materials new to science—developed only after years of patient labor and study, carried on at Cleveland.

The early forms of this battery have already withstood two years of severe service. The battery is extremely light and simple in construction, a very light one having driven an ordinary heavy electric automobile over a hundred miles on one discharge, covering average country roads and hills, as well as city streets and boulevards.

In achieving these results the inventor has utilized the work of the highest authorities in the field of chemistry in England, France and the United States, personally directing the work of experimenting in the home laboratories of these eminent scientists.

With this new battery, the heavy, cumbersome equipment and design of electric carriage now in use is no longer necessary, as the battery itself is of such light, yet strong, construction. From a scientific standpoint it is said to have an ampere efficiency of practically 100 per cent., and a higher curve of discharge than any battery heretofore known, being at the same time comparatively inexpensive to manufacture.

So strong have the claims for this battery proven that the whole series of patents covering it, together with other valuable and broad patents covering important features in automobile construction, electric motor gearing, motor suspension and mounting, and the simplest and most durable form of automobile trucks and running gears, have been disposed of to the American Bicycle Company, for a princely consideration. In fact, this company has already entered into extensive plans for the immediate and rapid construction of the new batteries, the use of which will at first be confined to vehicles of their own manufacture.

President Coleman was seen and found to be intensly interested in the subject, and highly elated over his company's success in securing the prize.

Through him it was learned that the inventor is Mr. Elmer E. Sperry. While it has been known for some years that he has been engaged on important work in this field, it is only recently that the results have been made public. He has been engaged in electric traction work ever since the earlier electric street cars were operated. He was the engineer for the syndicate which made the first bid for operating the elevated roads of Chicago by electricity. He has conducted some of the most important and difficult installations of electric mine locomotives of his own construction in various parts of the country, and is thoroughly familiar with electric traction in all of its forms. Mr. Sperry was one of the earliest to apply and adapt electricity to the operation of road vehicles, and among the patents becoming the property of the American Bicycle Company in this connection are a number of broad, basic patents.

The Sperry system of controlling automobiles by a single handle in place of a multiplicity of levers and foot treadles, is better known in France and England, where it has been widely adopted, than in this country, and has there received the endorsement of the leading automobilists. The natural manipulation of a single handle is found to vastly simplify the operation of the vehicle, entirely preventing confusion and the use of the wrong lever in times of emergency.

The Electrical Outlook in Siam.

Hamilton King, Consul-General at Bangkok, Siam, has sent the following report to the Department of State:

"The three companies that import electrical upplies report that their business has more than doubled during the last twelve months, while to my personal knowledge their orders during the last two months have exceeded those of any twelve previous months. There is a large and rapidly increasing business along this line in Bangkok, Siam, and there is no reason why the United States should not get a generous share. The tendency is toward the American market.

"The orders for the entire supplies for the new tramway, during the last two months, have been placed in the United States, with the exception of the rails. The order for the rails went to England, because the company thought they were unable to secure the peculiar kind they wished in any other country. This however, I believe is largely due to want of information on the subject, a cause which more familiar acquaintance with our manufacturers will no doubt set aside.

"A large quantity of the American electrical goods used here comes through London and European houses. This is another obstacle that can be removed by our manufacturers placing themselves in direct communication with importers here. American goods are in favor and the prices suit. The importers complain of American lack of promptness in attention to business. While goods are delivered here in three months from the time they are ordered from Europe and England, seven or eight months, and sometimes more, are consumed in getting them from the United States. This delay should be remedied. It is within my knowledge that answers to important cables have been delayed a full month.

"I quote from a letter just received at this office from one of the leading importers of this city:

"'My experience in doing business with the United States for the last ten years is that generally, in the United States you get for the same money a better article than in most European countries; but, with a few exceptions, American firms are not prepared for business with distant countries. Some of them have not even a cable address, and nearly all are slow and unsystematic in their correspondence. Shipping arrangements to Siam are also defective, as much as four or five months sometimes elasping between shipments from New York, whence we get most of our goods, and arrival in Bangkok. In consequence, we often prefer to order dearer or inferior articles from Europe to avoid delay and uncertainty.'

"The packing of the goods, I am pleased to report, has been materially improved during the last year. While one lot has come in a most unfortunate condition, yet the importers on the whole report satisfaction in this line now. It is to be hoped that the improved condition of shipping with all the far East that will come with our more direct communication with the Philippines will remedy some of these difficulties; and this, together with attention

Digitized by Google

on the part of our manufacturers to those points to which reference as already been made in this article, will put America in possession of her share of this trade in Siam.

"The leading importers of electrical supplies in this city are the Siam Electricity Company, Limited, the Siam American Trading Company and the Bangkok Dock Company."

LONDON NOTES.

(From our London Correspondent.)

New Electrical Projects.

Friday last, November 30, was the last day for registering applications for Parliamentary powers to be considered during the next session. Those filed include 103 provisional orders for electric lighting, 26 directly affecting electric tramways, and many which include electric traction among many other powers sought. Electric underground railways affecting London are as plentiful as blackberries in autumn. They are to run in all directions if Parliament allows them and the investing public furnishes the $300,000,000 which they are roughly estimated to cost. Certain London authorities are expressing the opinion that there should be some uniformity or system, co-operation of interests or general inter-connection in the laying out of London's great basement. Several electric power distribution schemes are on foot and appear to have some prospect of acceptance after the success of the schemes introduced last year.

Electric Traction on the Underground.

The Joint Traction Board of the Metropolitan and District Railways on Dec. 3 opened the tenders which have been submitted by English, American and Continental firms for working the line electrically. The proposals were considered for a time, but no definite action was taken in view of the important issues involved.

"Science and Engineering."

The London Institution of Electrical Engineers held its first annual dinner at the Hotel Cecil last night (December 3). Prof. Perry presided. Lord Kelvin responded to the toast "Science and Engineering." He said that all other branches of science and engineering had taken thousands of years to grow, but there was nothing in the discoveries or inventions of ancient times that led up to electrical engineering. It was a product, not merely of the nineteenth century, but of the last thirty years. He was convinced that there was a great future before it. Prof. Perry, who responded to the toast of "The Institution," said that the electrical profession was as yet but a baby, and the members of the Institution were the nurses, as ignorant, he might say, of what the babe was going to be in the future as nurses usually were. Among the other speakers were Mr. S. Z. de Ferranti, Lord Alverstone, Mr. Swinburne and Professor Rucker. Lieut.-Col. Crompton testified to the valuable services rendered by the Electrical Engineer Volunteers in South Africa.

The Electric Service of the Baltimore and Ohio Railroad at Baltimore

When the great double track tunnel under the city of Baltimore was constructed to shorten the route of the Baltimore and Ohio Railroad between New York, Philadelphia and Washington, the railroad company was the first to employ the services of electric locomotives for the handling of trains in the city limits. The ponderous engines are at present operated by means of the trolley system, getting their power from overhead wires.

The great cost of maintenance of this system and the consequent care in keeping it in repair, has induced the company to install the third-rail system, and work is progressing rapidly towards its completion.

The electricity is furnished by an electrical plant, which not only furnishes the power for the operation of the locomotives, but also the light for all of the Baltimore and Ohio properties in the city, as well as several private concerns.

In order to utilize all of the current and take up the surplus of electricity that is generated at the power house at moments when the locomotives or lights are not used, an enormous storage battery will be used, which will consist of 320 tanks made of hardwood lined with lead, each tank holding 39 plates, 19 negative and 20 positive. Each tank will weigh, with plates and electrolyte about 1,800 pounds, and the complete battery will have a capacity of 1,200 horse-power for a short period of time.

When the battery is put in service it will act as a reservoir of power, accumulating electricity while the locomotive is not in action and relieving the station of the load above the average by discharging into the line this accumulated current. To effect this, the station is only connected to the line through a booster, which is the combination of a motor and a generator. The generator is put directly in the circuit and is so designed that it only allows a certain amount of electricity to pass from the station to the battery and line. When the locomotive is not in service this current goes through the battery and charges it. When the locomotive is put in service the current is diverted to the line, and as by the nature of the apparatus no more can come from the power station, the battery must give out the extra current to operate. Thus the station will be operated at a greatly reduced and highly economical rate, and the extra power dispensed with may be put to other useful purposes.

When the battery is installed and the new third-rail system is placed in operation the railroad company will have, according to electrical experts, the most modern system of heavy electric haulage in the world.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

The Brandon (Man.) Electric Light Company is now building a power dam on the Little Saskatchewan River, about ten miles from Brandon. By this means about 800 horse-power can be developed and this can be increased later. Dynamos are to be put in next spring, when both power and light will be furnished.

Shipment was made recently of the largest motor that has yet been built in Canada. The motor was consigned to the British America Corporation of Rossland, B. C., and the shipment was made by the Royal Electric Company of Montreal. The motor is an S. K. C. two-phase machine, and its capacity is over 1,000 hp., and is to be used to drive the compressors and hoists at the mines. The total weight of the motor, boxed and ready for shipment, was 105,000 pounds, or 52½ tons. The weight complete of the motor with its accessories was over 120,000 pounds, or 60 tons, requiring two full cars to transport it across the continent.

The Nickel Copper Company of Ontario, whose large refining works are at the city of Hamilton, Ont., has begun operations on a large scale, and has placed in its new power house two 240 kw. and one 75 kw. S. K. C. generators; the former to drive the dynamos for the electrolytic process and the latter to drive the ore process. These three machines are being used as synchronous motors, taking the current from the Cataract Power Company's lines at 2,400 volts.

The city of Ottawa, at the last civic elections, voted largely in favor of municipal ownership and operation of an electric light plant. The special committee, appointed by the city council to report upon the feasibility of purchasing a municipal electric plant from the Ottawa Electric Company, has advised that no action be taken at present because of the terms which that company demands. The committee reports that the company does not want to sell its entire plant, but is willing to sell its street lighting plant, on condition that the city agrees to buy the power from the company for a period of ten years. The city, the citizens think, should not enter into a contract to take power for such a length of time. It is recommended that the city apply to the Ontario Legislature for such an amendment to the existing laws as will enable the city to arbitrate in its efforts to get a civic lighting plant, it being now debarred by the statute from so doing when a contract, as in the present instance, is still in force between a municipality and an electric company.

Meeting of the New York Electrical Society.

The 210th meeting of the New York Electrical Society was held at the College of the City of New York on the evening of December 12. Dr. Samuel Sheldon lectured on "Electrical Measurements of Precision." In the course of his talk Dr. Sheldon stated that commercial measurements are made with only such a degree of accuracy as is required by commercial conditions, while every possible refinement is employed in the making of measurements of precision. He added that the best of modern standard resistances are now made of manganin, which besides having a very small temperature coefficient gives very small thermal EMF.'s in combination with copper. Nearly all the alloys of nickel and iron have small temperature coefficients, but give a large thermal EMF. with copper.

After Dr. Sheldon's lecture, President Martin exhibited some 40 or 50 slides, chiefly night views, illustrative of lighting effects of the Paris Exposition.

The following resolutions were unanimously adopted:

Whereas, It is proposed to establish a national standardizing bureau; and

Whereas, Such a bureau would be of the greatest value and benefit to electrical science and industry in the United States, and assist in the further development of export electrical trade; be it

Resolved, That the New York Electrical Society expresses its approval of the legislation in furtherance of such an object, and

Resolved, That the Society associate itself with kindred bodies to secure the establishment of the bureau.

The following gentlemen were elected to membership in the Society: Edwin Rust Douglas, Ampere, N. J.; Rumsay N. Scott, 143 Liberty street, New York.

LEGAL NOTE.

A receiver has been appointed for the Grand Island (Neb.) Electric Light, Ice and Cold Storage Company, which was organized in December, 1898, with a capital stock of $75,000.

PERSONAL MENTION.

Mr. Rollo Jermyn of Oswego, N. Y., was recently appointed financial manager of the Syracuse Telephone Company.

Mr. Robert T. Tighe, the first man to establish telegraph lines in South America under Adrian C. Morse, died at his home in this city last week.

Mr. Charles P. Bowditch was recently elected a director of the American Bell Telephone Company and of the American Telephone & Telegraph Company.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended December 5:

Antwerp, 27 packages, $1,681; Argentine Republic, 207 cases, $8,530; Australia, 8 cases, $410; Brazil, 90 cases, $6,281; Bristol, 4 cases, $500; British Guiana, 55 packages, $1,444; British West Indies, 2 packages, $160; Central America, 34 cases, $953; Chili, 24 packages, $616; Copenhagen, 1 case, $115; Cuba, 430 packages electric railing material, $10,980; 64 packages, $5,390; Danish West Indies, 5 packages, $52; Ecuador, 7 cases, $257; Havre, 225 packages, $20,153; 6 packages motor material, $643; Leeds, 10 packages, $120; Liverpool, 63 packages, $6,622; London, 162 cases, $5,520; 209 packages, $31,978; Newfoundland, 25 packages, $277; Nova Scotia, 11 packages, $149; 3 boxes, $125; Peru, 8 packages, $167; 26 cases, $1,160; Porto Rico, 18 cases, $228; 1 package, $26; Santo Domingo, 118 cases, $2,589; Southampton, 16 cases, $1,815; Trieste, 1 case, $90; Venezuela, 33 cases, $176.

The following are the exports of electrical material, from the port of New York, for the week ended December 13:

Antwerp, 26 cases, $4,000: Argentine Republic, 87 packages, $3,534; 8 cases, $1,819; Australia, 62 packages, $8,749; 2 cases, $126; Barcelona, 2 cases, $63; Berwick, 4 cases, $288; Brazil, 27 packages, $1,303; 9 packages electrical railroad material, $1,091: Bremen, 1 case, $352; British East Indies, 26 cases, $5,203, 6,479 packages electrical railroad material, $118,500; British Possessions in Africa, 81 packages, $8,266; British West Indies, 701 packages, $1,382; Central America, 194 packages, $796; Christiania, 34 packages, $4,622; Cuba, 197 cases, $7,938: 1 elevator, $290; Dundee, 10 boxes, $950; Ecuador, 25 packages, $1,009; Elberfeld, 1 package, $3; Frankfort, 4 packages, $300; Genoa, 276 packages, $25,726; Glasgow, 77 packages, $2,452; 51 reels electric cable, $21,507; Hamburg, 87 packages, $5,795; Havre, 23 packages, $929; Hull, 60 packages, $17,824; Huddersfield, 2 cases, $92: Liverpool, 328 packages, $27,893; London 118 packages, 1,633; 9 cases, $1,696; Manchester, 275 packages, $37,815; 1 case, $389; Mexico, 270 packages, $2,772; 15 cases, $525; Milan 17 packages, $1,910; Newcastle, 34 packages, $5,695; 36 cases, $3,500; Odessa, 1 package, $14; Peru, 4 packages, $105; Porto Rico, 92 packages, $2,166; Preston, 2 cases, $41; Rome, 1 case, $17; Southampton, 4 cases, $195: St. Petersburg, 8 cases, $1,584: U. S. Colombia, 7 cases, $202; Venezuela, 10 packages, $149.

INCORPORATIONS.

The National Manufacturing & Electric Company, Assumption, Ill.—to manufacture electric light, steam heat, brick and tile. Capital stock, $25,000. Incorporators: C. C. Corzine, A. Cazalet and I. H. Cushing.

The Merchants' Electric Company, New Orleans, La.—to establish electric light, heat and power plants. Capital stock, $100,00. C. D. Crandall president.

The United Light & Power Company, New York City—to furnish electric light, power and gas. Capital stock, $1,500,000.

The Empire City Gas & Electric Company, Trenton, N. J. Capital stock, $500,000. Incorporators: George W. Lynch, Martin Callesch and John T. Underhill, all of Jersey City.

The G. R. Gray Company, New York City—to do an electric equipment business. Capital stock, $5,000, Directors: G. R. Gray of Jersey City, F. H. Shepperd and Pauline V. Shepperd of New York City.

The Barrington Electric Light & Power Company, Barrington, Ill.—to furnish electricity for light, heat and power. Capital stock, $25,000. Incorporators: Frank Robertson, Avery R. Hayes and W. R. Clasen,

The City Power Company, Jasper, Fla.—to do any business in which electricity or water may be an important factor. Capital stock, $20,000. Incorporators: W. H. Greene, M. F. Horne, C. W. Smith and B. E. Leonard.

The Fort Wayne, Dayton & Cincinnati Traction Railroad Company, Dayton, O.—to build an electric railroad. Capital stock, $20,000. Incorporators: S. F. George, A. J. Miller, C. W. Gebhart, D. W. Sinks, W. Hobbit, C. E. Swayne, C. A. Lucius, D. S. Waymire and E. J. Monnstephes.

The Long Island Electric, Gas & Water Company, Trenton, N. J. Capital stock, $500,000. Incorporators: G. H. B. Martin, F. R. Hansell and Max Phillips, all of Camden.

The Modern Machinery & Electrical Company, Denver, Col.—to manufacture and sell electrical machinery. Capital stock, $25,000. Incorporators: H. C. Russell, A. V. S. Saunders and E. S. McKinley, all of Denver.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 11, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

663,519. Electric Rail-Brake. Rudolf W. M. Schiemann, Dresden, Germany. Filed May 22, 1899.

663,600. Electric Railway. Theophilus P. Chandler, Philadelphia, Pa. Filed Oct. 22, 1900.

663,625. System of Electric Traction. Marco T. de Felice, Rome, Italy. Filed June 9, 1900.

663,700. Overhead Trolley System. Charles L. Leiby, Knoxville, Tenn., assignor, by direct and mesne assignments, to the Leiby Company, same place. Filed Dec. 5, 1898. Renewed Oct. 18, 1900.

663,740. Trolley for Electric Cars, William H. Earl, Painesville, O. Filed Aug. 14, 1900.

663,788. Trolley-Pole. William Schroeter and August Kautzmann, Dallas, Tex. Filed June 11, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

663,420. Arc-Light Hanger, George Cutter, Chicago, Ill., assignor to the George Cutter Company, same place. Filed March 10, 1900.

663,454. Electric-Arc Lamp. Frederick W. Martin and Frank Stewart, Hamilton, Canada, assignors of one-half to Brown, Boggs & Co., same place. Filed May 12, 1900.

663,467. Process of Producing Electric-Arc Lights, Ewald Rasch, Nuremberg, Germany. Filed May 7, 1900.

663,524. Incandescent Lamp. Samuel D. Washburn, Boston, and Clarence H. Tinkham, Cambridge, Mass.; said Tinkham assignor to Fred F. Rhodes, Boston, Mass. Filed March 12, 1900.

663,582. Flexible Supporting Structure for Electric Lamps, William F. Brewster, New York City. Filed June 12, 1900.

663,698, Electric-Arc Lamp. Josef H. Hallberg, Peabody, Mass., assignor to the Standard Thermometer & Electric Company, same place. Filed July 16, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

663,491. Controller for Electric Motors. Charles A. Dresser, Chicago, Ill., assignor to G. A. Edward Kohler and Franklin W. Kohler, same place. Filed May 10, 1900.

663,496. Electric Switch. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Feb. 11, 1899.

663,528. Electrically-Operated Clip for Tentering-Machines. William Whiteley and William Whiteley, Jr., Huddersfield, Eng. Filed July 27, 1900.

663,609. Dynamo or Motor. George L. Martin, New York City. Filed Aug. 24, 1900.

663,612. Circuit-Changer. Eustace Oxley, Lynn, Mass., assinor to the General Electric Company of New York. Filed May 29, 1899.

663,695. Electrical Interrupter. James M. Davidson, London, Eng. Filed June 7, 1900,

663,781. Circuit-Breaker. George W. Parsons, La Grange, Ill. Filed April 6, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

663,412. Telephone System. William W. Bennett, Mesquite, Tex. Filed Feb. 2, 1900.

663,510. Telephone-Switchboard. William S. Paca, Erie, Pa., assignor of one-half to Peter H. Adams, same place. Filed Feb. 16, 1900.

663,783. Selective-Signal System. Frank A. Pickernell, Newark, N. J., assignor to the American Telephone & Telegraph Company of New York. Filed Aug. 14, 1900.

MISCELLANEOUS.

663,460. Telegraph-Repeater. Charles D. Olsen and Thomas W. Carroll, Denver, Col. Filed Aug. 17, 1899.

663,461. Maximum-Demand Meter. Eustace Oxley, Lynn, Mass., assignor to the General Electric Company of New York. Filed July 31, 1899.

663,489. Electrical Connection. William B. Cleveland, Cleveland, O. Filed Feb. 7, 1900.

663,490. Method of Forming Electrical Connections. William B. Cleveland, Cleveland, O. Filed July 12, 1900.

663,605. Wire-Coupling. William Frankham, Canton, O. Filed May 24, 1900.

663,643. Sparking Igniter for Explosion-Engines. Frederick R. Simms, London, Eng., and Robert Bosch, Stuttgart, Germany. Filed Sept. 12, 1898.

663,653. Electric Igniter for Gas-Engines. Walter H. Cotton, Chicago, Ill. Filed Nov. 23, 1898.

663,659. System of Electrical Distribution. Henry R. Keat, New York City, assignor to the Westinghouse Machine Company of Pennsylvania. Filed May 1, 1900.

663,719. Electrolytic Apparatus. Hermann Becker, Paris, France. Filed June 26, 1899.

663,729. Sparking Igniter for Explosive-Engines. Louis S. Clarke and James G. Heaslet, Ardmore, Pa., assignors to the Autocar Company, same place and Pittsburg. Pa. Filed Aug. 30, 1900.

663,750. Electric Contact or Current-Taking Device. Ernest Greil and Emile Audiger, Paris, France, assignors to the Electric Lighting Boards, Limited, London, Eng. Filed Jan. 10, 1900.

663,760. Magnetic Ore-Separator. August Johnson, Moline, Ill., assignor to the Barnard & Leas Manufacturing Company, same place. Filed Feb. 2, 1900.

663,764. Magnetic Separator. Emil Kreuser and Hugo E. Langguth, Mechernich, Germany, assignors to Mechernicher Bergwerks-Actien-Vereis, same place. Filed June 11, 1900.

663,767. Fire-Alarm. Reason C. Livingston, Spring Valley, Minn. Filed March 24, 1900.

COMMERCIAL PARAGRAPH.

J. J. Reidy & Co., 311-331 East street, New Haven, Conn., makers of the Donnelly Improved Steel Climbers, are the only firm that make a business of manufacturing climbers exclusively. They report that more of these climbers have been sold in the Eastern and Southern States in 1900 than all other makes combined, and also say that the climbers are "not an experiment, but the result of 15 years of practical experience." In order to give linemen an opportunity of examining the climbers, and as a matter of business, as one pair will sell a good many and create a demand for them among the wholesale trade, as was the case in New York City and Richmond Va., the firm makes the following offer If you will send them $1.50 they will send you one sample pair only, any size you state, of Donnelly's Improved Steel Climbers, express charges paid by the firm. The fact that the Western Union Telegraph Company of New York City buy these climbers in lots of 100 pairs of a size at a time is practical proof of the excellent quality of them. The following are a few of the well-known firms who buy Donnelly's Improved Steel Climbers: Western Union Telegraph Co., Postal Telegraph-Cable Co., J. H. Bunnell & Co., E. J. Brooks & Co., the J. Jones & Son Co., Manhattan Electrical Supply Co., Manufacturers & Inventors' Electric Co., Western Electric Co., Patterson Bros., Stanley & Patterson, of New York City; New York and Pennsylvania Telegraph & Telephone Co., Elmira, N. Y.; Wallbridge & Co., Buffalo, N. Y.; Roe & Conover, Newark, N. J.; Doubleday-Hill Electric Co., Pittsburg, Pa.; McIntosh-Huntington Co., Cleveland, O.; Erner & Hopkins, Columbus, O.; Morley Bros., Saginaw, Mich.; National Electrical Supply Co., Washington, D. C.; James McGraw, Tower-Binford Electric & Mfg. Co., Watkins-Cottrell Co., Richmond Hardware Co., Richmond, Va.; Edward Lovell's Sons, Savannah, Ga.; Carter & Gillespie Electric Co., Atlanta, Ga.; A. Baldwin & Co., New Orleans, La.; Electric Gas Lighting Co., Pettingell-Andrews Co., Boston, Mass.; Belcher & Loomis Hardware Co., Providence, R. I.; Congdon & Carpenter Co., Bridgeport, Conn.; L. L. Ensworth & Co., Hartford, Conn.; N. T. Bushnell & Co., C. S. Mersick & Co., New Haven, Conn.

THE TELEPHONE WORLD.

Telephones for Rural Districts of Wisconsin.

The Farmers' Telephone Construction Company has commenced work in the township of East Troy in Walworth County, Wisconsin, and there the first system of its rural telephone service will be installed. Twenty-five subscribers have already been obtained in the village of East Troy, and it is reported that the farmers are taking up the scheme in a satisfactory manner. It was the original intention of the company to commence in the adjoining township of Spring-Prairie, but as the lines of the Wisconsin Telephone Company do not pass through that township it was concluded to begin in East Troy, where several long-distance lines meet in the village. The telephones which are to be put in are to be of the standard of the Wisconsin Telephone Company, with metallic circuits, and the service is promised to be first class in every respect. Under a new law passed by the last Legislature townships are permitted to issue bonds for the purpose of constructing telephone systems. East Troy township is now being asked to issue such bonds, to be delivered to this company upon the completion of the lines. The telephones are to cost $12 a year, and not more than four subscribers are to be placed upon one line. In the western part of that State a corporation of farmers operates a telephone system, but the yearly rental is $18. The East Troy system is to be connected with the long-distance lines of the Wisconsin Telephone Company, so that the farmers can talk with Milwaukee, Madison, Chicago or New York if they please. George N. Wiswell is president of the construction company, E. A. Wadhams is vice-president and Henry G. Goll is secretary and treasurer. The construction company expects considerable support in East Troy township from the summer resort people who are annually located along Lake Beulah and Crooked Lake, both of which are in that township. The company will take up other townships subsequently.

The Delaware & Atlantic Telegraph & Telephone Company, which is now controlled by the Bell Telephone Company, has decided to make a radical change in its system in Chester, Pa., by running its wires beneath the surface of the earth, where the lines will be protected from the terrific lightning storms of summer, the hail and sleet of winter, and the strong winds of March, comprising a trio of drawbacks with which the company has always had to contend. Conduits will be constructed along the main streets. In each square a pole will be erected for the distribution of the wires to the business places and residences of the company's subscribers. From the conduit to the top of each pole the wires will run in a cable. This system will have many advantages over the one now in vogue. The danger of falling wires will be averted and the number of unsightly poles lessened to one-third the number now in use. The company's engineer is now in Chester preparing plans and specifications for the route of the conduits. Considerable time will be required in making these preliminary arrangements, as efforts will be made to extend the underground circuit over the most propitious section of that city.

Articles of incorporation were lately granted to the Interstate Electrical Wire Subway Company of Kansas City, Mo., with a capital stock of $200,000. The incorporators are: W. S. Woods, William Huttig, J. J. Helm, W. A. Rule, W. W. Sylvester, H. C. Arnold and H. C. Ward. The company is the successor of the Kansas City Wire Subway Company, which had a capital stock of $20,000. It will continue the work of putting in a system of conduits for underground wire service begun by the old company. The stockholders will also organize an electric lighting company and contemplates forming an independent telephone company. Both of these companies will be distinct from the Subway Company, but will lease its conduits for conducting their wires.

The Independent Union Telephone Company of Buffalo, N. Y., was recently incorporated to maintain telephone lines between Buffalo, Rochester, Syracuse, Utica, Albany, Troy, and the cities towns and villages in the vicinity of cities named, in Central and Western New York. The company has a capital of $200,000, and the directors are Samuel B. Rawson, Irving H. Griswold, of Elyria, O.; George H. Frost, of Buffalo, and A. R. Smith of North Tonawanda.

The city council of Sherman, Tex., has granted a franchise to Frank B. McElroy and associates to operate a system of telephones in that city.

The aldermen of Batavia, N. Y., have granted a franchise to the Rawson Electric Company to install a telephone system in that city.

A telephone line is being put in from Macon to Milledgeville, Ga., with stations at Clinton, Gray and Haddock of that State.

Mountain Telephone System in California.

Forest Commissioner W. H. Border of Los Angeles, Cal., recently sent a force of rangers, under the superintendence of L. Newcomb, to begin construction on the telephone system to be put in operation between Sturdevant's camp across to the west fork of the San Gabriel River, a distance of fifteen miles. This system is to be used by the rangers and is expected to prove of great value in the fighting of future fires. It will be put up as fast as possible, although the severe damage done the recently-constructed mountain trails will cause considerable delay, both in this matter and in the projected purpose of planting tree seed on the reservation. The rangers' time will necessarily be employed during most of the winter months in repairing the trails.

Many complaints are being made of the inefficient telephone service furnished to patrons through the 38th street exchange of the local system in this city. Although the telephone service here frequently has become so unsatisfactory as to cause complaint patrons declare that never before were complaints so justified as those now being made against the exchange in West 38th street. It has been possible formerly to obtain some redress through appeals to the manager of the exchange, but even this recourse has ceased to bring about the desired results. One explanation offered for the inefficient service is that the exchange in West 38th street has been converted into a kindergarten for young persons who are striving to become telephone operators. No explanation is given, however, as to why one of the principal exchanges of the city should be selected for this kindergarten work. Nor is it known why the young operators after they have gained some knowledge of the work should be replaced forthwith by others who desire to learn. This is the company's secret and it is one which the exchange manager, following an established rule for reticence, is believed to take especial pride in not revealing to patrons who merely pay exorbitantly for a service which they are unable to get.

A direct independent telephone line will be constructed from Warsaw to Indianapolis, Ind., by Strauss Brothers, the principal stockholders of the Commercial Telephone Company of Warsaw, a new organization which recently purchased the property and business of the Warsaw Telephone Company, whose toll lines are already in connection with fifty cities, towns and villages in the counties of Kosciusko, Elkhart, Whitley, Marshall, Fulton and Noble, in Northern Indiana. The construction of a direct line to Indianapolis, will throw the Commercial Company into competition with the Central Union Company. Work on the new independent line will begin at once.

It was announced last week in Austin, Tex., that the national advisory board of the Electrical Workers' Union will order a strike of all the members of the order in the employ of the Erie Telephone system in sympathy for the strike of the employes of the Southwestern Telegraph & Telephone Company in Texas, which is a part of the Erie system. The strike in Texas was begun several weeks ago, and the places of all those who walked out have been filled by non-union workmen.

The local independent telephone lines in Mahoning County, O., are being widely extended. The new line from Poland to Calla is nearing completion. The United States Telephone Company has already commenced stringing wires to the State line. The line will be built out South avenue to the Boardman road running past Poland to Petersburg and on through Columbiana to the State line. It is expected to be in operation by January 1.

The Woonsocket & Wessington Springs, S. D., telephone system, about fifty miles of line, with four stations, was sold to the Dakota Central Company recently. The latter has just completed that line to Huron, giving Woonsocket direct communication with all stations in the northern part of the State. The line will now be extended to Letcher and Mitchell.

An independent company, the Farmers' Union, is being organized to construct and operate an independent telephone line between the villages of Jasper and Hedgesville, N. Y.

News from Montreal, Quebec, states that the stockholders of the Bell Telephone Company recently authorized the directors to issue $2,500,000 debenture bonds.

The Cumberland Telephone & Telegraph Company has lately put in an exchange at Adams, Tenn.

It is stated that a telephone connection with Sarasota Fla., is soon to be made.

A brisk telephone war is being waged in Lexington, Ky., between the Cumberland and the Fayette Companies. The Fayette Company is busy erecting poles all over the city. Eleven carloads of poles, two of wire and one of cross arms for the poles have been received. Ten thousand feet of new cable will be strung at once. A force of men is working, and the new exchange will probably be in operation shortly. The Cumberland Company in anticipation of the opposition has reduced its residence rate to $12 a year, and says that it will double the list of its subscribers.

The New England Telephone & Telegraph Company has decided to try an experiment in Gloucester, Mass. It will install telephones in the residences on free trial from now until the first day of April, 1901, as soon as the instruments can be installed. Each station will be equipped with a long-distance instrument and metallic circuit to enable the subscriber to call any out-of town party should they desire to do so. Free service however covers local calls only. The company's object in doing this is to introduce the telephone into the residences more extensively.

The directors of the Iowa Telephone Company, recently consolidated with the Central Union, met at Davenport, Ia., a short time ago, and decided to submit to the stockholders a proposition to increase its capital stock from $1,000,000 to $4,000,000. The money raised from the issue will be used in putting the wires underground and improving the service in many Iowa cities.

Telephone communication has been established beeween Huron and Woonsocket, S. D., completing a system connecting Huron with cities in every direction. The local plant has been greatly improved and now Huron boasts of being one of the best equipped cities for telephone communication in the Northwest.

The cable of the Sunset Telegraph & Telephone Company, containing practically all the long-distance lines out of Los Angeles, Cal., was maliciously severed with an axe a short time ago, entirely interrupting telephone connection with San Francisco and all points north and east. The police and fire alarm wires were cut at the same point.

Forty up-to-date telephones have lately been put in use at the Jackson Sanitarium at Dansville, N.Y., and a new switchboard is now being installed.

The Mutual Telephone Company of Creston, Ia., is about to have its lines in operation and a lively war is expected between it and the Iowa.

Inspector Grant of the Southwestern Telegraph & Telephone Company has lately been making a general inspection of all the exchanges of his company in Texas.

V. O. Hayden and M. H. Wade, who are installing the independent telephone system at Akron, N. Y., state that they have nearly 200 subscribers.

Arcade, N. Y., and Franklinville, N. Y., will be connected in the spring with Akron and Cuba, N. Y. All "Williams" instruments have been used in the above four plants.

The New England Telephone & Telegraph Company has acquired control of the Deer Island Telephone Company of Maine.

Foley, Ore., is now connected with a long-distance telephone.

TELEPHONE INCORPORATIONS.

The Reynolds County Telephone Company, Centerville, Mo. Capital stock, $1,000. Incorporators: J. J. Jamison, S. F. Cross, K. Z. Carter and others.

The Chagrin Falls Telephone Company, Chagrin Falls, O.; —to construct and operate telephone lines. Capital stock, $15,000. Incorporators: C. H. Hubbell, F. P. Shumaker, W. D. Brewster, J. W. Huchinson and L. Hubbell.

The Freeport Home Telephone Company, Freeport, O. Capital stock, $5,000.

The Corsicana Telephone Company, Corsicana, Tex. Capital stock, $50,000. Incorporators: F. B. McElroy, of El Paso; Frank C. Smith, H. M. Aubrey, both of San Antonio; Harvey Meyers, U. J. Howard, both of Covington, Ky.

GENERAL ELECTRICAL NEWS.

Lighting.

Anderson, Ind.—The Union Traction Company is preparing to furnish illumination by electricity to the various towns along the lines of its interurban electric road from its central power station at this place.

Asheville, N. C.—A. Field contemplates the erection of an electric light plant here.

Athens, Ga.—This city, it is reported, is seriously considering the question of erecting its own electric light plant.

Cloverdale, Cal.—The citizens of this place are agitating the question of erecting an electric light plant.

Clyde, N. Y.—Charles A. Lux, the promoter and head of the new electric light company here has made a five years' contract with the village to furnish light for the streets and other public places at the same price now paid by the village to the Clyde Gas & Electric Company.

Creston, Ia.—Mayor Skinner has received a communication from D. B. Lyons at Des Moines stating that when the council was ready he was prepared to make it a gas and electric light proposition.

Fayetteville, N. C.—This city will issue bonds for the erection of a municipal electric light plant.

Cullom, Ill.—This place will soon have an electric light plant.

Covington, Ky.—It has been decided to vote to issue $75,000 of bonds for the erection of a municipal electric light plant. W. E. Gunn, engineer.

Danville, Ill.—A movement is on foot to start a new electric light company here. Some of the former members of the Danville Telephone Company are connected with the new enterprise.

Gaffney, S. C.—This city will expend $11,000 in improving its electric light plant.

Humboldt, Tenn.—The B. C. Jarrell Company of this city will shortly erect a complete electric lighting plant here.

Johnstown, N. Y.—A new electric light company is being organized here.

Laurel, Miss.—The Laurel Light & Power Company has been chartered for the erection of an electric light plant.

Lincoln, Ill.—The city council has received a proposition from R. Wolfsberg to build and equip a municipal electric light plant.

Litchfield, Ill.—Bids will be received by this city until December 31 for supplying 60 or more 2,000 cp. open arc electric lights for street lighting; bidders are also requested to submit propositions for erection of an electric light plant of 100 lights capacity as above with 60 or more lights. Address H. Hall, city clerk.

Milford, Conn.—In all probability an electric light plant will be established here. George M. Gunn is supposed to be back of the movement.

Napanock, N. Y.—The reformatory here will be lighted by 1,500 electric lights.

Pawtucket, R. I.—An issue of $100,000 electric light bonds is contemplated by this city.

Pomeroy, Wash.—This city has a project for an electric light plant.

Portsmouth, N. H.—The entire plant of the Portsmouth Gas, Electric Light & Power Company has been sold to W. D. Lovell. The exchange means the expenditure of about $350,000 in improvements and alterations of the plant in this city.

Roseburg, Ore.—L. A. Walker has asked for an electric light franchise here.

Springfield, Mass.—The mayor will petition the State gas and electric light commissioners to investigate conditions in Springfield, with a view to ordering a reduction in the rates charged for electricity for lighting and power.

Thomaston, Ga.—This city will soon hold an election to decide the issuance of $10,000 in bonds for an electric light plant.

Thomasville, Ga.—The Thomasville electric light plant was sold lately at receiver's sale to Mr. Robert Gamble, who paid $15,800 for it.

Troy, Mo.—"Tink" Stocking, who gave Troy the telephone, proposes to install an electric light plant.

Valley Falls, N. Y.—It is stated that A. E. and N. B. Powers, who recently purchased the Lake knitting mill property in this place, intend to establish an electric plant for the purpose of furnishing light for the villages of Schaghticoke, Valley Falls and Johnsonville.

Wilmington, Del.—The New York capitalists who have secured a controlling interest in the Universal Conduit, Light, Heat & Power Company of this city will shortly begin laying conduits, and erecting an electric light plant here.

Street Railways.

Albany, N. Y.—The Albany & Hudson Electric Railway will be extended to Poughkeepsie. H. A. Benedict, superintendent, Hudson, N. Y.

Atlantic City, N. J.—Real estate owners and residents in the southern section of the city are petitioning the West Jersey & Seashore Railway Company to put in a trolley loop at Ventnor.

Bayville, N. Y.—There is some talk of a trolley line from here to Locust Valley.

Birdsboro, Pa.—Surveyors for the Reading Traction Company have been surveying a trolley line from Reading to this place. The road may extend to Pottstown, returning to Reading by way of Boyertown.

Cleveland, O.—The Cleveland Western Reserve and American Trust Companies of this city have purchased the Elgin, Carpenterville & Aurora Electric Railway near Chicago for $550,000. Another suburban railway is to be built near Chicago by Cleveland capitalists, many of whom are interested in the trust companies.

Columbus, O.—A company has been incorporated under the laws of New Jersey to build a line from Delaware to Magnetic Springs and other lines leading to Richwood and Marysville. The capital stock of the company is $400,000, and T. N. Kerr of this city is interested.

Decatur, Ind.—A. L. Scott, president of the Ft. Wayne Traction Company, J. W. Tyndall, and H. M. Romberg of this city, and W. H. Harkins of Portland, have made application to the city council for a franchise for an electric line. It is the intention to build the road from Ft. Wayne to Richmond.

Elwyn, Pa.—The officers of the Media, Middletown, Chester & Aston Trolley Company have practically secured the right of way over the entire route to this place.

Everett, Wash.—A franchise to furnish electric light and power and to build and operate electric street railway lines was granted to Ed. P. Burch of Minneapolis at a recent council meeting held here.

Findlay, O.—The Lima & Findlay Electric Railway Company has lately been incorporated with $20,000 capital stock to build an electric railway between Lima and this place. T. D. Roff, J. D. S. Neeley and L. Koch are interested.

Ft. Wayne, Ind.—An electric line is to be constructed from this city to Huntington.

Milford, Del.—Milford business men are discussing a project to run a trolley line from this place to Ellendale.

Newark, N. Y.—The consent of the railroad commissioners of the State of New York has been obtained to the construction of the Newark & Marion Electric Railway and by the first of the year the contracts for it will probably be let. The road will be ten miles long and it will cost about $150,000.

Painesville, O.—B. P. Foster of Cleveland, associated with other Cleveland capitalists, has applied for a franchise for an electric railroad between here and Fairport Harbor, 3 miles north.

Plainwell, Mich.—At a special meeting of the village board a franchise was granted the Kalamazoo Traction Company to build an electric road through this village.

Ridgeway, Ont.—A route for the proposed trolley line that will connect Fort Erie Grove with Crystal Beach and this village is being surveyed. Capital to build the road is assured and it will be rushed to completion.

Santa Ana, Cal.—The board of supervisors is preparing to advertise for bids for the electric street franchise for a proposed street railway from this city to Los Angeles via Anaheim, Fullerton and Whittier.

Versailles, Ind.—The residents of Ripley County are making an effort to have an electric or steam railway built between Greensburg and this city.

York, Me.—Wm. W. Nason, Ephraim Dyer, Frank M. Higgins, William R. Anthoine, Charles G. Moulton and Samuel O. Clark are interested in the York County Electric Railroad Company, formed for the purpose of building and operating a street railway 11 miles long in this county.

Manufacturing.

Libertyville, Ill.—The Freeman Power Supply Company, with a capital of $20,000, has been organized lately for the purpose of manufacturing and selling electrical and mechanical power. Ernest Freeman, M. M. Harms and Theodore K. Jackson have an interest in the company.

New York City.—The F. A. La Roche Company of this city was lately formed for the purpose of manufacturing electrical appliances, with a capital stock of $100,000. G. M. McWilliam, J. W. Avery and P. K. Stern are among those interested in the concern.—R. L. Steiner, Albert Lenz and Matilda Steiner are interested in the recently formed R. Louis Steiner Manufacturing Company of this city, which will manufacture gas and electrical fixtures with a capital of $15,000.

Company Matters.

Camden, N. J.—The following directors were reelected at the annual meeting of the Fairmount Park Trolley Transportation Company held last week in this city: Charles A. Porter, Robert H. Foerderer, Frederick S. Dickson, Dr. L. H. Filbert, Bernard Corr, Samuel C. De Coursey and John B. Peddie. The report of President Porter stated that this year's earnings compare favorably with the showing for 1899.

Chicago, Ill.—The Sanden Electric Company of this city has lately dissolved.

Reading, Pa.—William Jones and C. W. Lytton have formed a business partnership, known as the Reading Electrical Company. They will deal in electrical supplies and propose to ultimately form a stock company.

Rochester, N. Y.—At the recent annual meeting of the Standard Electric Construction Company the following directors were elected for the ensuing year: Birton A. Vandy, Arthur L. W. Miller and Walter H. Tobey.

Power and Transmission.

East Killingly, Conn.—New York capitalists have been looking over the old Young's mills property here with a view to securing an option on it for purchase in case the Providence and Danielson electric road is built.

Lockport, N. Y.—The Vanderbilt interests, through the agency of the Niagara, Lockport & Ontario Power Company, will build a power plant, rivaling in extent the Niagara Falls plant. They will cut a wide power canal from Niagara River to this city, also build a power transmission line to Depew, and make of Lockport and Depew electric cities.

Automobiles.

Ilion, N. Y.—It is stated that the Remington Automobile Company is making arrangements to permanently locate here where the enterprise originated.

Milwaukee, Wis.—The Milwaukee Automobile Company, of which W. H. Starkweather is president, is preparing to make shipments of its product to St. Petersburg, Russia, and London, Eng.

Sea Cliff, N. Y—This place is to have an automobile service next summer.

Toledo, O.—This city has an opportunity to try to secure an automobile plant employing 5,000 men.

Wilkes-Barre, Pa.—New electric busses were placed in regular service in this city a short time ago.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The Peoria, Ill., Gas and Electric Company has increased its capital stock from $500,000 to $1,000,000.

Books of Philadelphia Electric 4 per cent. trust certificates closed December 15 and will reopen January 2 for interest.

There has been incorporated under the laws of New Jersey the American Street Railway, Generating & Power Company, with a capital of $2,500,000.

Advices from Cincinnati state that the property of the Suburban Electric Company of Covington has been bought under foreclosure by the bondholders for $181,000.

The Lowell, Mass., Electric Light Corporation reports as follows: October gross earnings, $16,030; net earnings, $5,527. Four months gross earnings, $56,306; net, $15,503.

The United Traction and Electric Company of Jersey City, N. J., has declared a dividend of 1 per cent., payable January 2. Books close December 19 and reopen January 3, 1901.

The Twin City Rapid Transit Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable January 2. Books close December 27 and reopen January 2.

The Milwaukee, Wis., Street Railway Company will increase its capital stock from $3,000,000 to $15,000,000 and will use the additional capital in general improvements and in building a new power house.

The Westinghouse Electric and Manufacturing Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable January 2. Books close December 20 and reopen January 3.

The Brooklyn Rapid Transit Company's annual report for the fiscal year ending June 30 shows: Gross receipts, $11,768,550; expenses, $7,106,373; net, $4,662,177; charges and taxes, $4,135,405; surplus, $526,772; total surplus, $623,426.

A. B. du Pont has been elected second vice-president of the St. Louis Transit Company of St. Louis, Mo., and will assume charge of its operating department on January 1. Mr. du Pont has been the general manager of the Detroit Citizens Street Railway and Detroit Electric Company for several years past.

The executive committee of the Nassau Electric Railroad Company of Brooklyn has recommended to the directors the payment of a dividend of 4 per cent. on the preferred stock, payable December 31. No dividend was ever before paid on this stock. This company was leased two years ago by the Brooklyn Rapid Transit Company.

A cablegram from London states that H. F. Parshall, an American engineer, will succeed D. H. Louderback, of Chicago, as constructing engineer of Charles M. Yerkes' new underground railway. It is believed that Howard Abel, president of the Northwestern Elevated Railroad of Chicago, will be president of the Yerkes line.

The Mexican Telephone Company reports for October: Gross earnings, $15,717, increased, $2,408; operating expenses, $7,854, increased, $968; net earnings, $7,863; increased, $1,440. From March 1 to October 31: Gross earnings, $122,197; increased, $19,336; operating expenses, $67,671; increased, $7,262; net earnings, $54,526, increased, $12,074.

A bill which the Chicago Street Railway Commission is to present to the city council, will include recommendations for the municipal ownership of street railways, this question to be decided by popular vote, the unification of all street railway systems in the city, arbitration of labor differences, and the publication of detailed financial statements by the railway companies.

The deal between the Canadian General Electric Company, of Toronto, Ont., and the Royal Electric Company of Montreal, Que., has been fully consummated, and from it the latter company will get upwards of $1,000,000, as the result of its disposal of its manufacturing plant. This means the establishment of an electrical manufacturing trust in Canada with a capital of $60,000,000.

The Metropolitan Street Railway Company of New York City has declared the regular quarterly dividend of 1¾ per cent., payable January 15. Books close December 26 and reopen January 16. The balance sheet for the quarter ending September 30 shows: Gross earnings, $3,445,369; net, $1,890,333; other income, $162,937: total, $2,053,270: fixed charges, $1,128,985; balance, $924.285.

The general balance sheet of the Kings County Electric Light and Power Company as of November 1, 1900, shows: Assets—Property and construction, $3,259,210; Central Trust Company, trustee, $1,000,000; stock in other companies, $5,175,770; bills receivable, $175,000; accounts receivable, $55,072; cash on hand, $22,084; total, $9,687,136. Liabilities—Capital stock, $1,980,000; first mortgage, 5 per cent. gold bonds, $2,500,000; purchase money 6 per cent. gold bonds, $5,175,900; accounts payable, $606; profit and loss surplus, $30,630; total, $9,687,136.

The following statement has been given out by the Massachusetts Electric Lighting Association: "In answer to inquiries as to the attitude to be assumed by the association towards the petitions of several large street railway companies recently published, which, upon their face, seem to look towards a possible entry into the field of electric lighting or power by those companies, we are pleasd to be able to say that we have received the most positive assurances from those in control of the companies referred to that they entertain no such purpose, and that their petitions for legislations are not intended to extend their powers outside of the field of the street railway busines. These assurances are of such a character, and come from such sources that we are justified in the statement that no efforts to secure legislation antagonistic to electric lighting companies will be made by the street railway companies above referred to."

EDITORIAL NOTES.

The New Year.

This issue of ELECTRICITY will be the last of the Nineteenth Century to reach its readers. The issue after this will be the first of what might be termed the new era, and it is our purpose and intention to make ELECTRICITY during the new year even more instructive and attractive than ever before. ELECTRICITY'S Educational Series, which is attracting so much attention and by means of which we hope to help electrical workers, will be continued for some little time, and when that series has been completed we can safely promise that another series of equal importance to the electrical fraternity will be begun. We propose to give even more attention than heretofore to the General Electrical News Department, in order that electrical engineers and manufacturers may know at an early a date as possible of electric lighting and street railway contracts about to be let or of electrical supplies wanted. The articles on general subjects will be carefully selected with a view to their instructiveness or novelty.

We anticipate a prosperous year and sincerely hope our friends, readers and advertisers will have no cause to grumble during 1901 at what fate has in store for them.

* * *

Wireless Telegraphy for the Weather Bureau.

In his annual report to Congress, the Secretary of Agriculture devotes considerable space to the work accomplished by the Weather Bureau during the past year, during which time important extensions to the service have been made. Recognizing the advantage that would result to commerce and navigation by the establishment of wireless electrical communication between vessels at sea and exposed points on our lake and sea coasts, and also between islands along said coasts and the mainland, the Weather Bureau was directed to systematically investigate the various methods of electrical communication without wires. The progress made is eminently satisfactory to the Government officials. New appliances have been devised for the transmission of signals, and receivers have been constructed that probably are more delicate than any heretofore made. Messages already have been successfully transmitted and received over fifty miles of land, which presented a rough and irregular surface, conditions most unfavorable for the transmission of electro-magnetic waves. It is believed that the efficiency indicated by such transmission overland is sufficient to operate successfully over several hundred miles of water. The apparatus used is capable of further improvement. The Secretary has expressed the hope that the time is near at hand when the great number of craft employed in the coastwise commerce of the United States and over its great inland seas will be placed in instantaneous communication with the numerous stations of our Weather Bureau, which are located at all important points. The matter is one of such great importance to our commerce that Secretary Wilson has authorized extensive experimentation, which, from the success so far attending the efforts of the officials, will be vigorously prosecuted.

* * *

An Electro-Magnetic Gold-Extracting Process.

Prof. Elmer Gates, of Washington, D. C., who as will be recalled claimed some years ago to have invented a method of utilizing the sun's heat for power purposes, has recently taken out patents on a so-called hydro-magnetic separator, by means of which he proposes to separate gold from magnetic iron or magnetite.

There is nothing especially new or startling in a magnetic separator, as a number have been invented. Mr. Thomas A. Edison brought out one several years ago, which has been made use of to a limited extent with excellent results, so it is claimed. Prof. Gates' apparatus, however, differs somewhat from those already in existence, and a few words regarding it will therefore be in place.

As already stated the object of Prof. Gates' device is to remove from the gold-bearing sand the magnetic iron which such stuff always contains, as a preliminary to separating the gold as in the ordinary way, either by washing or by amalgamation. The apparatus consists of a copper drum, inside of which is an electro-magnet. The core of the magnet is made up of a number of iron plates with fluted edges on the pole face of one end, likewise within the drum, but which approach their fluted edges close to the inside of the copper periphery of the latter. Above is a hopper through which the sand is poured. As the gold, silica and magnetite passes through the hopper it neces-

Digitized by Google

sarily touches the side of the drum, which is kept revolving by means of an electric motor. The drum, owing to the magnet inside of it, draws the particles of magnetic iron out of the sand which naturally adhere to its surface while the sand drops into a receptacle below the machine. The particles of iron while magnetically held against the drum are moved downward by it over the wavy lines of force of the fluted magnet face and vigorously shaken so as to detach all foreign matter.

In practical mining work the gold would be left in with the silicious sand, which would subsequently to put through one of the ordinary processes, with a view to separating it from the precious metal. The magnetite once removed, the separation of the gold from the sand becomes comparatively easy, so much so that it is claimed that from two to five times as much of the yellow metal is derived from a given quantity of the raw material. The inventor states that his method is simplicity itself, and further that it costs but three cents for each ton of sand treated.

Another advantage pointed out by the Washington professor is that the iron removed from the sand in the manner just described is an exceedingly valuable by product. At an expense of eighty-five cents a ton it is proposed to reduce it by means of the electric current into lumps, in which form it may be sent to any smelting works.

As to whether the optimistic views of the inventor of this process will be fully realized in practice remains of course to be seen, but it certainly seems more plausible than the scheme suggested some time ago by Prof. Gates for utilizing the energy of the sun.

* * *

The Theft of Electricity.

In several foreign countries, especially in Germany, the question has from time to time been brought up as to whether electricity could be stolen. In spite of the fact that to the ordinary mind it would certainly seem as though a person who deliberately appropriated current generated by the coal paid for by other people should be held liable for theft, the courts have in several instances ruled otherwise. With a view therefore to settling this question once for all, at least in New York State, an amendment was added during the last session of the Legislature, to section 651 of the Penal Code, which reads as follows:

A person who willfully or with intent to injure or defraud: First—Connects a tube, pipe, wire or other instrument or contrivance with a pipe or wire used for the conducting or supplying illuminating gas, fuel, natural gas or electricity in such a manner as to supply such gas or electricity in any burner, orifice lamp or motor where the same is or can be burned or used without passing through the meter or instrument provided for registering the quantity consumed, or

Second—Obstructs, alters, injures or prevents the action of a meter or other instrument used to measure or register the quantity of illuminating fuel, natural gas or electricity consumed in a house or apartment, or at an office or burner, lamp or motor, or by a consumer or other person or persons other than a State inspector or deputy inspector of gas meters or an employe of the company owning any gas or electric meter, who willfully shall detach or disconnect such meter, or make or report any test of, or examine for the purpose of testing any such meter so detached or disconnected: or

Third—In any manner whatever changes, extends or alters any service or other pipe, wire, or attachment of any kind, connecting or through which natural or artificial gas or electricity is furnished from the gas mains or pipes or wires of any person, company or corporation without first procuring from said person, company or corporation written permission to make such change, extension or alterations; or

Fourth—Makes any connection or re-connection with the gas mains, service pipes or wires of any person, company or corporation furnishing to consumers natural or artificial gas or electricity, or turns on or off or in any manner interferes with any valve or stop-cock or other appliances belonging to such person, company or corporation and connected with its service or other pipes or wires, or enlarges the orifice of mixers, or uses natural gas for heating purposes except through mixers, or electricity for any purpose without first procuring from such person, company or corporation a written permit to turn on or off such stop-cock or valve; or to make such connection or re-connections, or to enlarge the orifice of mixers or to use for heating purposes without mixers, or to interfere with the valves, stopcocks, wires, or other appliances of such person, company or corporation as the case may be, is guilty of a misdemeanor.

As a result of this law, which was certainly much needed, the electric lighting companies have been keeping a close watch on suspicious consumers and only recently many persons have been prosecuted in the courts of this city for tampering with electric light and power meters.

Investigations by the Edison Electric Lighting Company has revealed the fact that numerous schemes have been adopted for falsifying the reading of meters. One consisted in bridging the meter, or connecting a wire to the feed and exit wire. Another device for cheating the meter was to bore two holes in its top and with a wire to move the index hands back. Mr. Edwards, auditor of the company mentioned above, is reported as saying:

"We are not suffering any more now from this stealing of the current than we ever were. We are making it warm under the new law for the offenders. That is all. We know pretty nearly everybody who is stealing from us, and we are getting evidence together to convict them. When we bring the charge home to an offender, we propose to press it to the full extent. It is practically impossible for anybody to steal electricity from us for over a month without our finding it out. Obtaining the evidence is not so easy. But there is no device for tampering with the meter that will not leave behind it traces, which a skilled electrician must recognize at once. As conditions were prior to the passage of the law by the last Legislature, we were practically helpless. But now that we have a law under which we can act we are going to push all cases of this kind to the limit."

THE report of the Commissioner of Patents for the fiscal year ended June 30 shows a total of 26,540 patents granted, including reissues and designs. There were 1,660 trademarks, 682 labels and 93 prints registered. Patents that expired numbered 19,988. Allowed applications forfeited for non-payment of the final fees were 4,052. Of the total of 39,815 applications recived 2,263 were for designs, 90 for reissues, 1,759 were for caveates, 2,105 for trademarks, 872 for labels and 127 for prints. On July 1 applications awaiting action by the Patent Office numbered 3,564, which is between 500 and 600 more than on July 1, 1899. The number of applications for patents, etc., received during the fiscal year just closed was 5,000 greater than during the preceding year.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

THE Standard Underground Cable Company of Pittsburg, Pa., has commenced shipments on the contract for cables and equipment of the electric light and power plant for the City of Mexico. The contract will aggregate $200,000.

AN electric generating plant is being installed by the signal corps post at Fort Myer, Virginia, for furnishing electricity for storage batteries used for instruction and other purposes at that post and also for motor vehicles.

IT was recently learned that the Westchester, N. Y., Automobile Club intends to purchase some of the old bicycle repair shops along the roads leading to the Ardsley Casino, the Knollwood Country Club and the Country Club of Westchester. These shops will be changed into supply stations for automobiles.

THE River Plate Electric Light and Traction Company at Rosario, Argentina, has plans prepared for the new installation, in accordance with the decision of the Arbitration Court. It will be remembered that the work will cost nearly $500,000. A great deal of underground work is to be done. Quantities of new machinery, tools and other material will be required by the company.

SECRETARY LONG has submitted estimates for additional improvements for the Brooklyn Navy Yard, aggregating $113,000. He asks for $35,000 for connecting the pumping plants of Dry Docks 1, 2 and 3 with the electric power house; $50,000 for the enlargement of electric power plant, $3,000 for elevator in building No. 33, and $25,000 for heating, lighting, and elevator in office building No. 22.

A MEETING of the board of governors of the Automobile Club of America was held last week in the office of President Albert R. Shattuck, 11 Broadway, New York City. The most important matters for discussion were the proposed moving to permanent club quarters and the effort about to be made for a test case regarding the presence of gasoline automobiles on ferryboats. No immediate runs are scheduled, the chief interest in that respect now being centered in the proposed test case of all varieties of automobiles, which will be held early in the spring.

IN whatever respects Philadelphia may be slow that cannot be said of one of her trolley lines, which is used to distribute the morning papers. Starting from the heart of the city the car travels at the rate of thirty-five miles an hour, including at least one stop every three-fourths of a mile. It is an experiment

Digitized by Google

by the Union Traction Company to test the maintenance of high speed and the evenness of schedule time under conditions peculiarly favorable for securing exact factors for all the problems it is sought to solve. Every trip is observed by electrical experts, the induction is estimated, the power measured, the state of the metal, the thermometrical and barometrical conditions noted, as well as the humidity and fog at the different elevations along the line, and when 1,000 trips have been made the data thus gathered will be considered, with a view of formulating a result to be applied in such directions of economy and accelerated speeds as may be opened up.

ACCORDING to the "Amur Gazette," an extraordinary telephone line has been built by the Amur Goldworks Company at its place on the Seja River, to another establishment on the River Aldan. Instead of insulators, which are difficult to obtain in Siberia, empty bottles have been used on which to support the line. Anyone who is conversant with the characteristics of the Russians, says the London "Electrical Engineer," can quite believe that there was an ample supply of empty bottles in the district.

KEEPING everlastingly at it brings success, is what a well-known firm of national reputation has for its watchword; and while it must be admitted that it is true, yet it is as well to know where to keep everlastingly at it, so that good efforts may not be expended on barren territory; for this reason it may not be out of place to again call attention of electrical equipment manufacturers to the almost undeveloped field that awaits patient work in Mexico. The report of the British Consul, Jerome, especially calls the attention of his countrymen to the fact that electricity is being very largely used in the development of the various industries being established throughout Mexico, as well as for lighting purposes and for street railroad systems. Electric batteries imported into Mexico during the past year amounted to a total weight of 100 tons, at a total value of $45,-547.92, and he also does not fail to call their attention to the further fact, a matter of congratulation to American manufacturers, that of that amount and value no less than 72 tons were imported from the United States and of the remainder, only one and one-half tons were imported from England.

ONE of the large agricultural implement manufacturers has about completed arrangements to engage in the manufacture of the Borsig Electric plow for the American markets. This machine has come into very general use in Europe and will probably become popular here. During the last 14 months no less than 482 farms in Europe have introduced that plowing system. Especially amongst the beet root sugar factories is the plow finding a ready sale. The electrical plow works by means of two wire cables, which run in a parallel direction over the field, about 3 feet from each other. At one end an anchor-carriage is used, which is so constructed that the carriage body itself is never influenced by the working plow, as the anchoring device is fixed to a kind of portable crane attached to the frame of the carriage. Thus the carriage frame itself can never get out of its original direction. As soon as the plow returns to the motor the anchor is lifted out of the soil by the motion of the idle plow cable, and this exactly for the distance which is required for the anchor setting in again. In most cases where the electrical plow is used at present the current is derived from a central station, from which it is transmitted to the field by means of overhead wires. From this overhead wire a movable isolated cable is, at a given point, conducted to the motor car. This latter is placed on one end of the field to be plowed, and the anchor carriage at the opposite end of the field. The plow then travels between the motor car and anchor carriage. As soon as one furrow is completed motor and anchor cars advance exactly one-furrow's space when the work starts again. The whole plant is so constructed that from one and the same branch cable, 90 hectares or about 230 acres, can be plowed.

THE matter of the transmission of power from Niagara Falls to Toronto, Ont., has been taken up by two local corporations, the Toronto Street Railway and the Toronto Electric Light Company. Although no decisive action has yet been taken by either of the companies, at least one of the concerns engaged in the development of power at the Falls is confident of selling a large quantity in Toronto. While three power companies intend to operate at the Falls, the Ontario Power Company has been the most active in endeavoring to find its market away from that district. This company is utilizing the natural advantages offered it, by which it secures its water power from the Welland River, the water being carried over the cliff into Queen Victoria Park, will it is estimated, be able to produce as much power with an expenditure of $5,000,000 as the American company has secured at an expenditure of $15,000,000.

THE largest corundum mill in the world, which is situated in Raglan Township, Renfrew County, Ont., was started on the 21st inst., and when in full operation, it will turn out more corundum than all other plants in existence. The full capacity of the mill is 15 tons of corundum per day, reclaimed from 100 tons of rock. The orders are chiefly from great engineering works in Europe and the United States. Mr. George C. Edwards, of Bridgeport, Conn., is president of the company.

A DISPATCH from Honolulu states that wireless telegraphy is meeting with much success in Hawaii. A large number of messages have already been transmitted from one island to another. The company which is seeking to put the system in operation lately chartered the yacht La Paloma to cruise among the islands to test the possibility of communicating with ships at sea from land. The tests are said to have been successful. Experiments are now in progress to determine the best locations for the stations on several islands. When this has been completed stations will be connected by ordinary telegraph lines with the centers of population, and regular transmission of commercial business will be begun.

IN a leading article the "Elektrotechnische Zeitschrift" comments on the increasing practicability of equipping standard-gauge railways for electric traction, says the "Electrical Engineer," London. Since considerable distances are involved by railway work, the transmission of energy by means of high-tension multi-phase currents is a fundamental basis for such projects opines the authority in question. But the transformation of the energy prior to its final conveyance to the propelling motors of the trains may be accomplished in various ways. As a matter of fact, three systems have already been tried. One of these consists in the conversion of the high-pressure multiphase currents into continuous currents of moderate pressure by means of fixed transformers and rotary converters placed in sub-stations. A second system consists in converting the high-pressure multiphase currents into multiphase currents of moderate pressure, and conveying the same to the trains through three separate conductors. In this case at least two special conductors are requisite, while the rails may constitute the third, and the trains would, of course, be equipped with multiphase motors. The third system consists in conducting the high-pressure multiphase currents by means of three overhead wires direct to the train, which is equipped with transformers and multiphase motors. As regards the relative values of the three systems, expert opinions differ.

THERE are three street cars on the Indianapolis, Ind., line that disturb no man's sleep and frighten no horse into hysterics with demoniacal noises. They are equipped with wheels made by the Noiseless Wheel Company of Indianapolis—C. E. Kregelo, president; Israel Hoagland, vice-president and inventor; A. W. Wishard, secretary-treasurer. The wheel is patented. It looks like other car wheels, and is made in different sizes and weights for street cars and railroad freight and passenger cars. Cars in Chicago have been equipped with them for six months, and demonstrations of their advantages over common wheels have been made to different railroad companies. The body of the wheel and the tire are separate. The tire is bolted to the wheel, and between them is a cushion of hard pressed paper. The chief advantage of the wheel, it is averred, is not that it is noiseless, but the ease with which repairs may be made. Now, when a car wheel goes flat, the car must go out of use for a week or more, be taken to the shop, the truck removed, and a new wheel substituted for the old one. It is said that this wheel can be produced for $20.

A SPECIAL cable dispatch from London to the N. Y. "Sun," dated December 22, states that Prof. J. A. Fleming, the well-known electrician of London University, is understood to be engaged in important experiments in connection with a novel form for the transmission of electrical energy. There is reason to believe that the professor has discovered the means by which such power can be distributed without wires by utilizing the ether as Marconi does for ordinary signaling.

A TURNTABLE for trolley cars has been patented by an Ohio inventor. It is so arranged that when the car is driven on it the front wheels rest upon two rollers coming up through the track, and, by gently starting the motors, these revolve under the car and communicate their motion through proper gearing to the turntable itself, and thus the car is turned around by its own power, the trolley swivelling on its base and staying on the wire. The crew of the car do not have to descend from it, and it is asserted that the apparatus works very quickly and successfully in practice.

"Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 7.

INSTRUMENTS FOR ELECTRICAL MEASUREMENTS.

Electrical measurements cannot be made as we would measure steam and water, for in the latter case we have substance; however we must have a means for measuring and calculating which will be just as reliable electrically as the other measurements are in their relation to steam and water.

An electric current represents energy, and consequently if properly applied will do work—the amount of work performed depending on the amount of electrical action. Calculation of rate of flow and pressure or voltage then depends directly on the effect produced. Let us get this a little more clearly in another way. An electric current will induce magnetism and the strength of that magnetism will depend entirely on the amount of current flowing, for increase the rate of flow and you will increase the magnetic strength produced by it. Now if we employ this magnetic condition to do work then the amount of work done will indicate the strength of the magnet, which in turn depends directly on the amount of current flowing. If we manufacture an instrument based on this principle then you can say that a certain amount of work done will represent a certain rate of flow of the electric current.

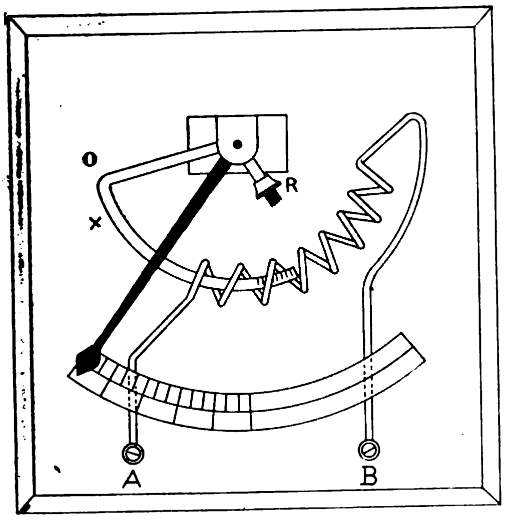

FIG. 1.

Fig. 1 gives an illustration of this method of calculaton and also is a diagram of an instrument widely used to-day for measuring the amperes flowing in a circuit.

If you connect a circuit to the posts, A B then the current will flow through the coil producing a magnetic condition that in turn will act on the iron X, which will be drawn into the coil and the distance that it will be drawn will depend entirely on the strength of the magnetic condition acting upon it. By having an arrow attached, as described in the figure, it gives a means of reading the effect produced.

Suppose we connect an instrument of this description in series with a standard ammeter, we could then mark off on the scale points indicating the amount of current flowing, corresponding of course to the amount indicated by the standard instrument, for the same rate of flow would be acting on both instruments. This would be what is known as calibrating an instrument. Before calibrating a set of this kind see that the arrow points to zero after the instrument is permanently placed. If it be a little out either way the adjusting screw, R can be used to set it correctly.

By properly balancing this system a fairly uniform scale can be secured and for special purposes the scale can be expanded to any point desired. This type, however, has an inherent defect in measuring direct current, due to the iron not responding readily to slight changes of current, which makes a sudden increased reading lower that it should be and a sudden decreased reading higher than it should be. This is sometimes called "magnetic lag." However, when alternating currents are measured this does not come into play, but in that case the precaution must be taken to laminate the core so that local currents will not be induced in it. This law will be taken up later on in the series.

The use of the magnetic law in measuring is used in other ways than that just described. A very popular one is where the measuring coil consists of a number of turns of fine wire, wound on a rectangular form, and this coil rotates in a concentric annular space through which passes a permanent magnetic field. When current enters this coil, it tends to deflect it from a fixed position, which is reacted by differential springs; in this way deflections can be obtained which are proportional to the current flowing.

Although the magnetic effect is the means most commonly used for measuring, there are two other effects produced by an electric current that may be used as a basis of calculation. They are the electro-chemical effect and the heating effect.

Electro-chemical measuring is based on the fact that an electric current flowing from one metal to another through an acid solution will decrease the weight of one and increase the weight of the other by the action of electroplating. This effect will depend on and be governed by the amount of current flowing. An example of this method is the Edison meter, not so commonly used now as it was several years ago.

The third method of measuring depends upon the heating effect of a current when passed through a resistance, together with the fact that a wire will expand when heated. This method is used very little outside of the laboratories.

TO MEASURE ELECTRIC PRESSURE.

The most familiar means of measuring pressure is to measure the amount of current or rate of flow which it causes to pass through a known resistance. An instrument for doing this is called a voltmeter, and the principle it involves is just the same as that described in Fig. 1, except in a voltmeter the coil of wire should be of a known high resistance. Supposing in our voltmeter the coil that is acting upon the iron core to be of 100 ohms. Now according to Ohm's Law one volt will force .01 of an ampere over that resistance while 100 volts would force 1 ampere over the 100 ohms, so that the instrument while being effected by the amount of current flowing must necessarily indicate the pressure causing it to flow, whereas the mechanism of a voltmeter and an ammeter may be the same and depend upon the magnetic effect produced by the flow of current for their action, yet they differ in the fact that an ammeter must necessarily have a low resistance coil, for it is connected in series with the circuit and carries all the flow, while a voltmeter in measuring pressure must be connected across the circuit and have a high resistance, for it only requires enough flow to operate the instrument, the amount of current flowing over it of course depending on the pressure forcing it.

THE MEASUREMENT OF RESISTANCE.

All useful and practical methods of measuring electrical resistance depend directly upon the indication of Ohm's Law. The simplest means of calculating a resistance is by comparison, that is, by comparing the effects produced in a known resistance to that of an unknown, or by adjusting a known resistance until the amount of current flowing over it will be equal to that flowing over the unknown resistance when both circuits are connected to a common source.

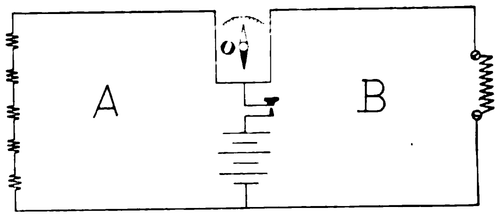

FIG. 2.

In Fig. 2, suppose the resistance in circuit A be the known and circuit B be the unknown resistance which it is desirous of measuring.

If both circuits be equal, the amount of current flowing in each will be the same, but if not equal, more current will flow over the lower resistance than over the higher.

If a galvanometer be placed in the circuits at point O the needle will indicate which side has the greater amount of flow, and if both be equal it will be affected by both the same and remain at the zero point. So by plugging in or out resistance in the known side we can get both equal and when such a condition is indicated by the needle the circuit is supposed to be balanced. The unknown will then be known, because it will be equal exactly to the known side.

HINTS ON THE USE OF INSTRUMENTS.

Never connect an ammeter across a circuit. Always place it in series.

A voltmeter should be connected across the poles of the circuit to be measured.

To measure resistance by an ammeter, divide the voltage by the amount of current flowing which will give the resistance. Suppose for example, there were 110 volts pressure and the amount of current which that pressure was causing to flow through a circuit showed on an ammeter to be 2 amperes, then the resistance of the circuit must be 55 ohms.

To calculate voltage by the use of an ammeter, multiply the amount of current caused to flow over a known resistance by the resistance, which will give the voltage. For example, if an ammeter shows that there be 5 amperes flowing in a circuit of 2 ohms resistance then the pressure must be 10 volts.

Article No. 8 will be entitled "Coils and Coil Making."

The Manhattan Elevated Railway of New York has ordered from the Allis Company of Milwaukee 8 engines of 5,000 hp. capacity each.

THE NERNST LAMP.

The London "Electrician," in its issue of December 7, describes as follows the Nerst lamp as manufactured by the Nernst Electric Light Company, Ltd. When the Nernst lamp patents were disposed of, it will be remembered that the Westinghouse Company acquired the patents for the United States and Canada, Messrs. Ganz & Co., the rights for Austro-Hungary and Italy, and the Allgemeine Elektricitäts Gesellschaft the patents in Great Britain, Germany, and other European countries. Unless, therefore, the last-mentioned company sells its patent rights for Great Britain to a British manufacturing firm, it appears more than probable that the Nernst lamps used in England will be made in Germany. Each company that has acquired Nernst patents has been left to work out a practical form of lamp on its own lines, and the samples shown us differ in several respects from the model adopted so far by the German company. Neither of the two types are yet on the market, but that of the Nernst Electric Light Company (Ltd.) has been shown as the pattern that will soon

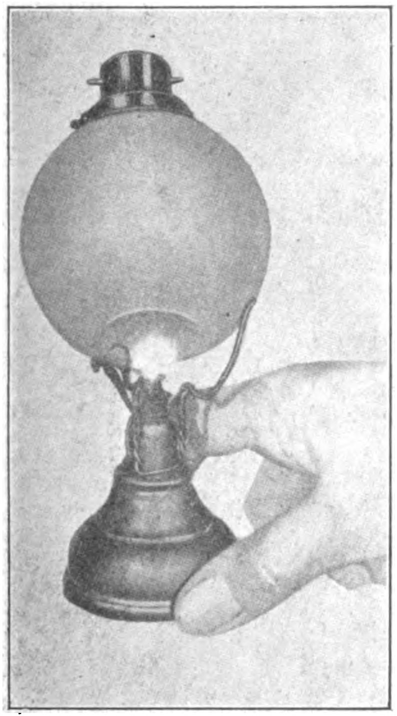

Fig. 1.—Simple Lamp with Spirit Lighter.

be made in quantities—although it is understood that orders for shipment would not yet be accepted, and that prices could not be quoted at present.

The efficiency adopted by the company is somewhat lower than what has hitherto been associated with the idea of the Nernst lamp. Although the incandescent rod of refractory material, which for convenience we will still call the "filament," may furnish light at an efficiency of little more than 1 watt per candle, a resistance absorbing a certain amount of power has to be placed in series with the filament in order to steady the current. As is well known, the filament of the Nernst lamp is made of a material which does not conduct at low temperatures, but becomes a conductor at higher temperatures, and at these higher temperatures its temperature coefficient for resistance has still a fairly high negative value. It is, therefore, necessary to add a resistance coil with a positive temperature coefficient in series with the filament to prevent instability, and this coil has a resistance equal to 10 per cent. of the resistance of the lamp. This does not account for the whole decrease of efficiency below what was originally attributed to the Nernst lamp, for the lamps made by the company are made to a standard of 1.7 watts per candle power; so it may be reasonably concluded that a lower temperature is employed than in the original experimental lamps, and that this may account to some extent for the much longer lives, of 500 to 1,000 hours, and even more, which are now obtained.

Our illustrations show the form the Nernst lamp has taken under the hands of the company, through the work of Mr. Drake, Mr. Sheppard, and the consulting engineer, Mr. James Swinburne. Fig. 1 is an external view of the simple lamp, which requires a spirit lamp as lighter, Fig. 2 shows the same lamp without its cover, Figs. 3 and 4 illustrate a self-lighting lamp, and Fig. 5 is a pattern for high-candle powers. The simple lamp for lighting with a spirit lamp has a globe open at the bottom, as shown in Fig. 1. The filament, which is of about the thickness of a pin, is held between platinum wires, the junction between the platinum and the filament being covered with a blob of similar material as that of which the filament itself is composed. This junction gave a good deal of trouble at first, especially the one at the anode or + pole in the continuous current lamp. It was found that considerable heating took place here, and that, at a spot near the anode, the filament itself diminished in thickness. To overcome this, the platinum wire wound round the end of the filament is brought to the surface of the covering material, and in the case of larger lamps projecting pieces of platinum, to assist in the dissipation of the heat, have been tried with success. The thicker wires seen in Fig. 2 leading to the platinum wires are of nickel. The steadying resistance is of fine platinum wire, wound on a piece of unglazed biscuit porcela the latter material being employed for all the non-metallic parts of the renewable portion of the lamp.

Air is necessary for the burning of the lamp, at all events with continuous currents. This is probably because a supply of oxygen is necessary to prevent electrolysis of the magnesia, which is the basis of the filament, or perhaps

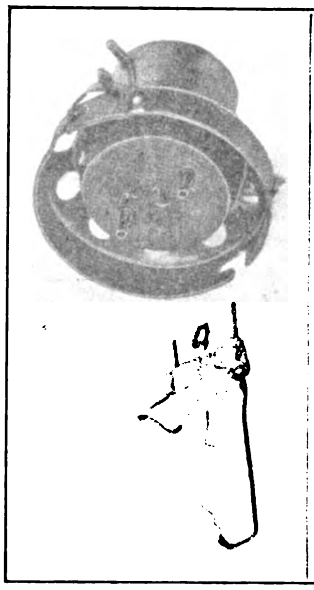

Fig. 2.
Simple Lamp Without Globe.

Complete.

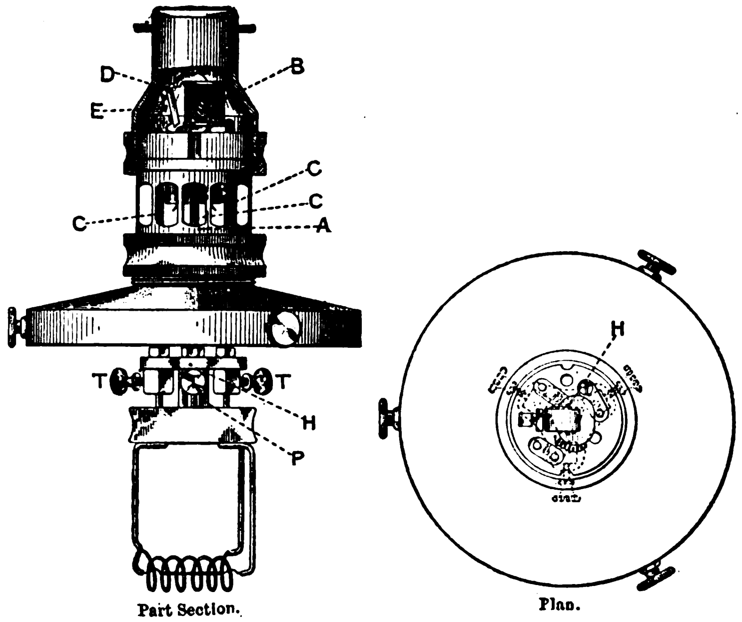

Fig. 5.—50-cp. 100-volt Lamp. Half Size.

rather to effect the reoxidization of the magnesium which is the product of the electrolysis. The top of the cap which fits over the globe is therefore perforated with a few large holes, the self-lighting lamps being in globes closed at the bottom. In the self-lighting lamps, the platinum spiral which acts as the heater forms part of the renewable portion of the lamp. This is clearly seen in Fig. 3.

It is proposed to supply these renewals at a low cost, receiving in part payment the old ones in which the filament is burnt out. The white spiral seen in the figure is of porcelain —the platinum spiral is formed of a long piece of fine wire wound on the small porcelain rod before the latter is bent into a spiral shape. This bending is done in the blowpipe after the platinum coil has been wound on it. The self-lighting lamp has a resistance coil of platinum wire similar to the simple lamp, but the renewable part has three contacts to allow of the heating coil being switched off as soon as current passes through the lamp. This coil always remains in position round the filament, however. Two of the contacts are made by hooks in the base-plate fitting into the two eyes seen in the figure. These are placed at different centers so that the right connections must be made in putting in the filament block. In some later lamps the still simpler expedient has been adopted of having one hook shorter than the other. The third connection is an ordinary plunger and spring, as in an ordinary center-contact incandescent lamp-holder. Above this base-plate, and in what may be called the hood of the lamp, is the electromagnet for cutting out the heating coil as current passes through the filament, the actual cap which fits into the ordinary lamp-holder being above this again. Since this base-plate and the cap and hood fitting over it is to all intents and purposes a lamp-holder, it is difficult to see why the company adapt all their lamps to fit into any ordinary holder as well, thus introducing an unnecessary intermediate contact and retaining the plaster of paris cap, which is the weakest part of the carbon filament lamp. Moreover, by dispensing with the old lamp-holder, the price of the Nernst lamp complete would have to be compared with that of the carbon filament lamp plus its lampholder, and this would tend to overcome the initial cost difficulty. Lamps with B C terminals should only be required, one would think, when it is indispensable to utilize existing fittings.

As there is no vacuum space between the filament and the lamp cap, the latter would get very hot in the case of lamps of large candle-power and damage the insulation on the electro-magnet. To meet this Mr. Drake has devised the form of lamp shown in Fig. 5. The connections CCC between the two parts of the lamp pass through a sort of cage, A, and an air space is thus interposed. It is to be hoped, however, that the bare connections CCC will be insulated, when the lamp is put on the market, as at present they afford too great a temptation for making short-circuits. The contacts between the renewable part and the permanent part of the lamp are in this case formed by ordinary block terminals TTT, and the correct connections are ensured by cutting a hole, H, of trapezoidal section, in the part of the base in the center of these, into which fits a similarly-shaped projection P from the base of the removable part. The steadying resistance is not seen in the figure; it is similar to that employed in other lamps.

The electromagnetic device, shown in Fig. 5, for switching out the heating coil is the same as is employed in the other self-lighting lamps made by the company. The small coil B is in series with the filament, and, as soon as current passes through it, the armature D is attracted, breaking the contact E, which is in series with the heating coil. Although very simple, this device gave considerable trouble to design so as to avoid humming in the case of alternating-current lamps. A still more compact form is now being made experimentally, in which the axis of the coil is parallel to the base, and the contact is in the base itself. This modification, together with the device of making the contact hooks long and short, instead of at different centers (already alluded to), reduces considerably the size of the lamp.

The company's offices are lighted with Nernst lamps of various sizes, and their appearance compares not unfavorably with carbon filament lamps and fittings. Comparing them with the cumbrous self-lighting lamps exhibited by Mr. Swinburne at the Society of Arts about two years ago, it is evident that great progress has been made. Whether, however, the shareholders of the Nernst Electric Light Company, Ltd., were well advised in investing £270,000 (out of a total capital of £320,000) for the patent rights in distant lands of an invention which it has taken two years of experiment to prepare for the market, is another matter. No doubt we shall learn the present opinion of the shareholders on the question at the annual meeting of the company which will be held shortly. In the meantime we congratulate Mr. Swinburne and the technical staff of the company, on the good work they have done in developing Nernst's invention into what promises to be a thoroughly practical and useful piece of apparatus, calculated more than ever to cheapen and popularize electric lighting.

I.—HIGH TENSION POWER TRANSMISSION PLANTS IN FRANCE.

BY FRANK C. PERKINS.

Monophase Plant at Allevard-les-Bains

A number of high tension power transmission plants have been installed in France using polyphase and monophase alternating current apparatus. While the Swiss Engineering firm, Compagnie De L'Industrie Electrique of Geneva, has been introducing a direct current high tension system designed by M. Thury, with more or less success. They have not been extensively used in France, and England, but have been operated in Italy and Switzerland quite successfully.

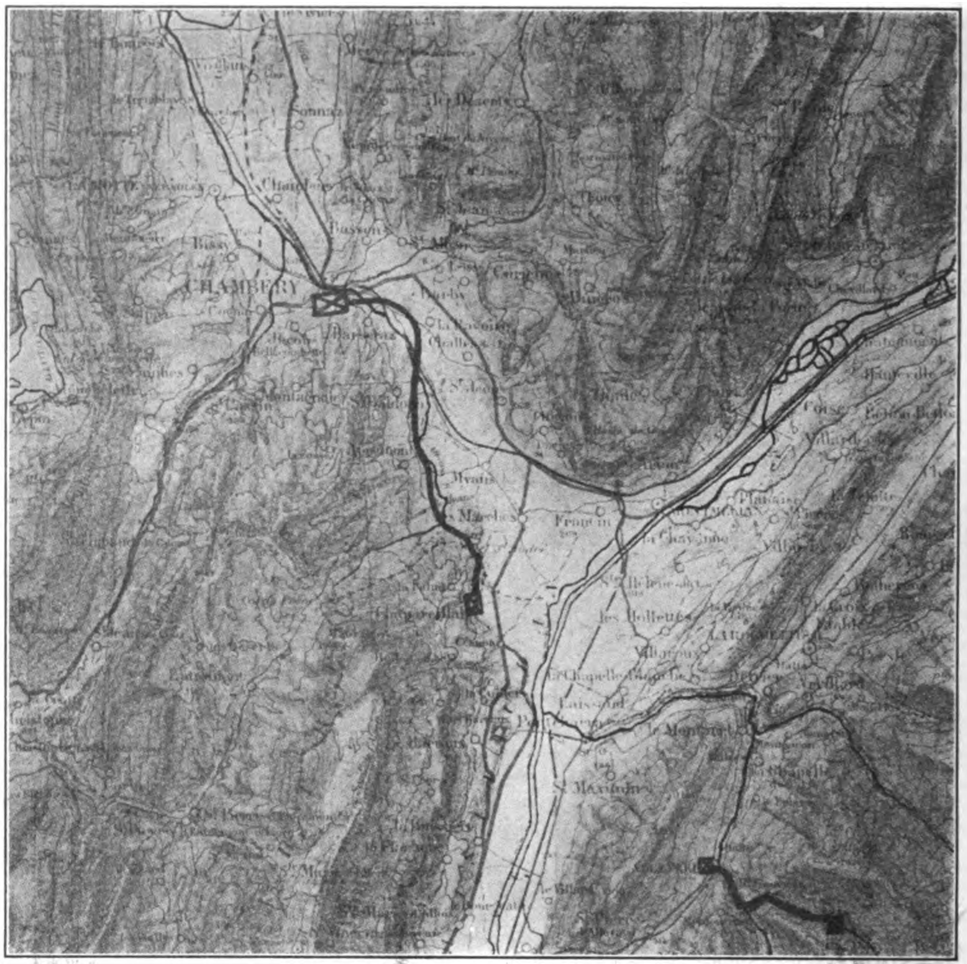

FIG. 1.—HIGH TENSION MONOPHASE AND TRIPHASE TRANSMISSION LINES IN ALLEVARD-LES-BAINS AND CHAPAREILLAN-CHAMBERY, FRANCE.

Alternating current power transmission plants have been a specialty with the Société L'Eclairage Electrique of Paris for a number of years. The earliest installations had a line potential of 5,000 volts. Plants of this character were introduced at St. Sebastian, Chapareillan-Chambery, Lourdes and at Amparo (Bresil).

It was found necessary as the distances were increased to raise the potential in order to reduce the losses and reduce the first cost for copper conductors. It was therefore decided that the plant at Blanjeu should be operated at a potential of 10,000 volts. This plant gave such good satisfaction and the difficulties encountered in insulation were so successfully

met that a later project for lighting thirty-five villages in the valley of Gresivanden was carried out to completion, using a line potential of 12,000 volts. This plant was located at Lancey and the apparatus installed was of the monophase alternating current type.

The next increase of potential was on the line between Grenoble-Voiron and Engins. This installation is of the three-phase type and 15,000 volts were successfully used.

The length of the lines increasing with each installation (Fig. 1), the potential was also necessarily increased to save loss on the line, and first cost of circuits. In the above gradual increase from 5,000 volts to 15,000 volts, the generators were in every case low potential machines of either the monophase or tri-phase type, and the increase of voltage was attained by the use of step-up static transformers.

The power transmission line of the Allevard-les-Bains (Isere) installation, Fig. 1, is five kilometers long. At various points on the transmission line small sub-stations, Fig. 2, are equipped with transformers of various sizes for supplying local distribution. The power house at Allevard is divided into two parts, separated by a stone wall, the turbines being installed in one part and the generators, switchboards and exciters in the other, Fig. 3. The generator room contains two alternators designed by M. Labour, of Paris, electrical engineer of the firm Société L'Eclairage.

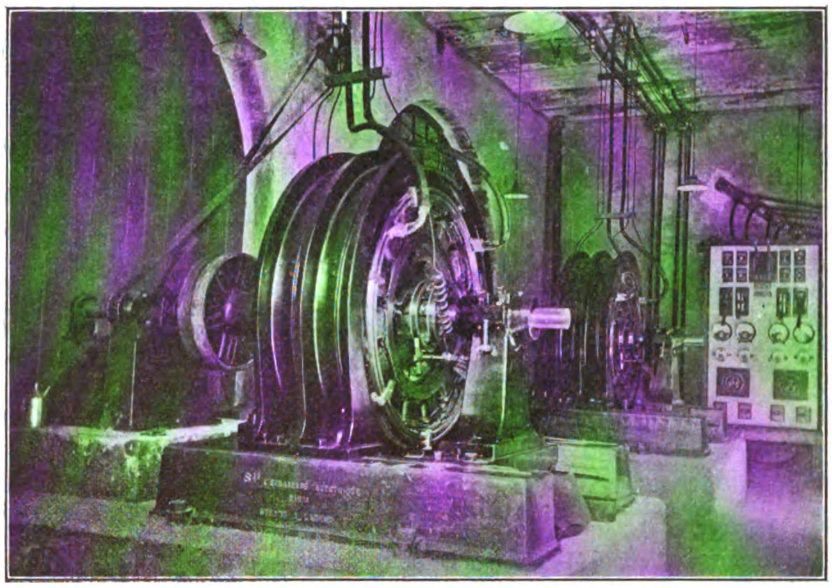

Fig. 3.—Generator Room at Allevard-les-Bains.

Fig. 2.—Step-down Transformer Sub-station on the Allevard-les-Bains (Isere) Line.

These machines are directly coupled to the turbines in the adjoining room. The alternators are of the monophase type having each a capacity of 150 kilowatts. The primary voltage generated by the machines is only 120 volts and step-up transformers are used for raising the potential on the line to 2,400 volts. At the various small sub-stations, Fig. 2, which are equipped with transformers, the voltage is transformed down to 110 volts for the low tension lighting circuits. In this country the transformers would be placed on poles or on the sides of the buildings, and separate transformer buildings are not usually provided as abroad unless the capacity is of such size as to require a special foundation.

The next installation considered will be that at Chapareillan-Chambery Transmission Plant, and illustrations will be given in the next issue of "Electricity" of exterior and interior of the power house belonging to this system located at Chapareillan.

ELECTRIC OSCILLATIONS*.

The experiments in wireless telegraphy which have been going on of late lend an additional interest to the subject of "Electric Oscillations and Electric Waves," which Professor J. A. Fleming, M.A., D.Sc., F.R.S., has selected as the theme of his Cantor lectures, the first of which was given at the Society of Arts on the evening of November 26. He defined electric oscillations to be an alternate current of high frequency, of as much as a million, or several million alternations, per second. Frequency exercises a great influence on the behavior of currents. For instance, in dealing with direct currents, resistance is one of the chief factors of which we have to take account, but with increased frequency the phenomena connected with inductance and capacity became of far greater importance, particularly the former, and we have to part company with many of our notions on the subject of electricity. With currents of high frequency, the flow is not necessarily in the same direction in all parts of a given conductor, nor is its volume constant. Alternate currents of low frequency must have a closed circuit for their generation, but oscillations may occur in a straight wire. To produce oscillations, ordinary mechanical means are useless; it is impossible to move coils of wire with sufficient velocity to produce them. The only method is by means of Leyden jars

*From "Engineering," London.

Digitized by Google

and condensers. The oscillation, however, is not due to the condenser itself, but to a peculiar property in air. This property is that air is a perfect non-conductor until the pressure reaches a certain critical value, when it suddenly breaks down and becomes a conductor. To obtain oscillations, two qualities are necessary in the circuit—capacity and inductance. as mechanical analogies aid the comprehension of electrical phenomena, Dr. Fleming expresses the conditions necessary for oscillation as follows:

1. A self-recovering displaceability.
2. Something like inertia.
3. Suddenness of release.

The displaceability makes the thing go when let loose, and the inertia makes it overshoot the mark, so that it can come back. The release must be sudden, or else the thing will slide slowly to a position of rest and stay there. For instance, if mercury be raised in one leg of a U-tube by blowing into the other, and then released by letting the air go, the column will oscillate up the two legs alternately several times. If, however, the air be allowed to leak out slowly, the mercury will come steadily to a position of equality in the two legs.

It was suspected long ago that the discharge of a Leyden jar was not in one direction only. In 1842 Henry remarked that the magnetism of needles by the discharge was very irregular, sometimes in one direction, sometimes in another, and sometimes not at all. In 1847, Von Helmholtz dealt with the same subject, and in 1851, Thomson (Lord Kelvin) gave the first exposition of the phenomenon. Dr. Fleming showed by an experiment that the discharge from an induction coil through a vacuum tube is in one direction only. It is visible to the eye that this is so, for the illumination is different at the two ends of the tube. When, however, the discharge is obtained from a Leyden jar, the appearance of the glow is uniform, and does not change on the connections being reversed. Such a discharge viewed in a revolving mirror is seen to be double, flowing first in one direction and then in the other; it is oscillating. Prof. Boys has photographed the discharge by arranging lenses around a rapidly-revolving wheel, and throwing the pictures of the spark on to a sensitive plate. The result is a series of marks, like a succession of Morse dashes. From the speed of the wheel it was calculated that, in this instance, there were 3,000 oscillations per second.

Below a pressure of 300 to 400 volts air is a complete non-conductor. Above that pressure, as already stated, it breaks down, and the sparks pass. It is not completely understood what the action is, but it is thought that the molecules break up, and the electrically charged ions go in opposite directions. J. J. Thomson has shown that no electric force will break up a molecule, but it is possible that vibration may do it. A coherer has much resemblance to air in this respect. Under a pressure between 1 and 2 volts it scarcely conducts at all; but under a higher pressure it instantly develops high conducting powers. The following table gives the dielectric strength of various insulators:

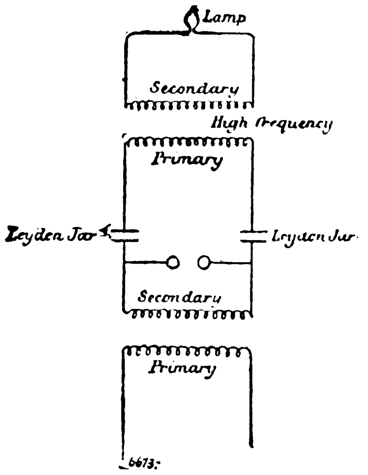
	Kilowatts per Centimeter.
Micanite	4000
Mica	2000
Ebonite	54
Linseed oil	83
Cotton seed oil	67
Air 2 millimeters thick	57
" 16 " "	27

The last two lines are very noticeable, the thinner layer having the greater strength. The greater strength of oil, as compared with air, suggests its use in the spark gap. It has been tried by Dr. Fleming and also by Marconi, but the results were not encouraging. It has more strength, but there is less suddenness in the giving way. It does not snap.

The air between two charged balls is in a state of strain. When the air breaks the strain vanishes and we get current, and the current sets up lines of magnetic force. The current also expends its energy in reproducing the state of strain, and so the action goes on backwards and forwards, the strain and the rupture following each other until the energy is frittered away.

A frequency of a million per second does not mean that there are a million oscillations, but that the oscillations are at that rate. Generally there are a few—four or five—oscillations, and then a long wait, the intervals being comparable to a clock giving twelve ticks and then standing twenty-four hours; then giving twelve more ticks, and so on. The problem awaiting solution is how to make the oscillations persistent.

Oscillations decay and die away. They are damped by the alternating magnetic field they set up. This field was demonstrated by Dr. Fleming by the use of two coils, one contain-



ing a spark gap and the other a tiny electric lamp. When the oscillations were set up by the discharge of the Leyden jars, the lamp lighted up, although its coils were some feet away from the other, and not close, as shown in the figure. "That," said Dr. Fleming, "is not wireless telegraphy, but wireless electric lighting." When he interposed his body between the two coils it made no apparent difference, and neither did a board. A piece of thin perforated zinc, however, completely cut the influences, and the light failed. If the frequency had been of the alternating-current order of 100 per second the zinc would have had very little effect, as its electric resistance was great. But as the frequency is raised the influence of the zinc increases. If cooled to absolute zero, so as to become a perfect conductor, it would cut off low frequency vibrations also. The explanation of the action of the zinc is that the primary coil sets up Foucault currents in it, and these create a magnetic field on the other side of opposite phase, which balances the field set up by the first coil.

The two coils constitute an oscillating transformer. If the second has a large number of coils, then it becomes a step-up transformer. In making such an apparatus there are certain conditions to be observed, and these are generally opposite those governing the usual transformer. It is important that the turns of the coil shall be kept far apart. The closer they are the greater the inductance, and inductance throttles the discharge. Ebonite does not make a satisfactory non-conductor for such coils; glass is the only substance to use. One coil is put in the interior of a glass jar, and on the outside there is a single layer of gutta-percha covered wire. A coil like this will raise the potential to any desired point—10,000 or 40,000 volts. The great point is to space the turns of the coil far apart, to prevent impedance. Only one layer must be used, and more turns be gotten by lengthening the glass core. Dr. Fleming showed sparks 6 feet long, in vacuum tubes obtained in this way.

Secondary oscillations can not only be created in metallic conductors, but also in gaseous conductors, that is, transformers may be made in which the secondary conductor is gas. Dr. Fleming showed a glass cylinder with hemispherical ends, exhausted to 1 millimeter of mercury. This cylinder was some 6 inches in diameter and 10 inches long. Around its center was a coil of six turns of wire, and when an oscillating current traversed this coil the gas in the cylinder lit up in circular rings of light. It was a very pretty and striking experiment. When the cylinder was wrapped in silver paper there was no effect. The metal film acted like the zinc plate by creating a magnetic field opposite in phase to the first.

The inductance caused by convolutions lying close together was strikingly illustrated by Dr. Fleming. He used two wire coils as at first, but in series with the second he put a very loose helix of wire on a non-conducting core. The coils of the helix could be drawn wide apart, like the threads of a worm, or pushed close together like a fine pitched screw. In the former case the lamp shown in the diagram burned, but when the coils were suddenly pushed together it was extinguished. Iron, also has the effect of increasing inductance, although Hertz thought that iron could not be magnetized by oscillating currents. A bundle of copper wire placed in the coil makes very little effect on the light, while a bundle of iron wire of the same size effects a marked diminution of the light.

High frequency currents do not penetrate the mass of a conductor, but keep on the surface. Rayleigh showed long ago that alternate currents have not a uniform flow over the cross-section of a conductor, and gave a formula for the resistance of a conductor to alternating currents. This, however, does not apply to high-frequency currents. With a frequency of a million per second, a current does not penetrate into an iron conductor more than one two-hundredth millimeter; it penetrates into copper 15 millimeters. The skin effect increases the apparent resistance, but decreases the inductance. There are, broadly, three kinds of resistances to consider: (1) Ohmic resistance; (2) resistance to alternating current of 100 periods; and (3) resistance to oscillating currents.

The New Jersey State Grange, Patrons of Husbandry, concluded its annual session recently. A number of resolutions were adopted one of which demands the repeal by the Legislature of the law of 1896, which prohibits trolley companies from carrying freight, and alleges that the law was in opposition to the interests of the farmer.

BIRDSEYE VIEW OF THE PAN-AMERICAN EXPOSITION.

It is promised for the Pan-American Exposition that it will surpass in beauty any previous exposition in the world's history. It is also expected that it will outrival its predecessors in many other ways, for at no time have such wondrous achievements in all arts, such perfection in the hundreds of trades been attained. Accompanying this article is a birdseye view of the Exposition plot, showing the magnificent work in its completed state.

The symmetrical grouping of buildings will be at once noted by the observer. Beginning at the formal approach, just north of the lake, the eye follows northward between two rows of ornamental columns to what is known as the Forecourt. East of this are the State and Foreign Buildings forming in themselves a very interesting feature of the Exposition. Near these, also, are the buildings for the special ordnance displays, representing the products of several hundred manufactories in this line of work. West of the Forecourt will be the outdoor horticultural displays and the Women's Building. We cross now the Triumphal Bridge which will be remarkable for its tall piers richly ornamented with statuary, the product of the genius of Karl Bitter, the Director of Sculpture, and other famous sculptors. On either side are the Mirror lakes which form a part of the Grand Canal, more than a mile in length, which surrounds the main group of buildings. We come next to the Esplanade, which is nearly two-fifths of a mile long and 450 feet wide. The western end of the Esplanade is enclosed by the Horticulture, Graphic Arts and Mines Buildings. The eastern end is shut in by the Government group of three large buildings. Sunken gardens with elaborate fountains and many groups of sculpture occupy the two arms of the Esplanade and the decorative features throughout this broad space are very numerous and beautiful. North of the Esplanade is the Court of Fountains, with the Ethnology Building on the right and the Music Building on the left. Two subordinate courts also open into the Esplanade from the north, the one on the right being known as the court of Cypresses and the one on the left as the Court of Lillies. Next, north of the Ethnology Building on the right, and fronting upon the Court of Fountains, is the Manufacturers and Liberal Arts Building and on the opposite side the Machinery and Transportation Building. In the Court of Fountains is a large pool, having an area of about two acres and containing many beautiful fountains. Proceeding again northward we come to the Mall, a broad avenue, half a mile long extending from the eastern boundary to the western gate of the Exposition. Fronting upon the Mall on the right is the Agriculture Building and on the left the Electricity Building. We now arrive at the most conspicuous feature of the Exposition, the massive Electric Tower, 391 feet in height. This tower stands between the Court of Fountains and the Plaza, in a broad pool, about two acres in extent. This will be the most ornamental feature of the great Exposition and will be the centerpiece for special and elaborate electrical illumination. Immediately north of the Electric Tower is the Plazza, with its beautiful sunken garden and bandstand in the center, the Propylasa, or monumental entrances at the north, the entrance to the Stadium on the east and the entrance to the Midway on the west.

At night all the buildings will glow with the soft radiance of thousands of electric lights, making a scene of unrivaled brilliance and splendor. More than 200,000 lamps will be used in the electrical illumination.

It should also be added that the Midway at the Exposition will be the most extensive and novel that has ever been prepared. It will be 3,000 feet long, having more than a mile of frontage. Over thirty very interesting features, many of them covering several acres, will make up the gigantic collection of wonders.

The Athletic features of the Exposition will be shown in the Stadium, which covers about ten acres of ground and contains a seating capacity for more than 12,000 people. All of the exhibit buildings will be filled to completion with the very latest products of Pan-American genius and industry, and will offer an opportunity for every inquiring mind to learn a most interesting lesson of New World progress and civilization.

The power for Exposition uses is furnished principally from Niagara Falls, which are situated only a few minutes' ride from the Exposition grounds. Buffalo is a city of nearly 400,000 population and is preparing in every possible way for the reception of millions of visitors in 1901.

Meeting of the Northwestern Electrical Association.

The Ninth Annual Convention of the Northwestern Electrical Association will be held at the Hotel Pfister, Milwaukee, Wis., commencing on Wednesday morning, January 16th, next. Reports and papers on subjects of special interest to central station men will be read and discussed. The hotels and railroads have made special rates for the occasion, and a large attendance is expected. Secure hotel accommodations in advance. For rooms, exhibit space, etc., apply to manager Hotel Pfister; and for wiring, current, etc., for exhibits, to

Digitized by Google

Mr. O. M. Rau, 451 Broadway, Milwaukee. For information as to railroad rates, special train and car arrangements, address Mr. James Wolff, chairman, 320 Dearborn street, Chicago, An attractive entertainment programme has been arranged, and a pleasant and profitable time is assured to all who attend the convention. The association extends a cordial invitation to all electrical men.

LEGAL NOTE.

James D. Feeter of Little Falls, N. Y., has been appointed receiver for the Dolgeville, N. Y., Electric Light and Power Company for the purpose of foreclosing a mortgage of $50,000 held by the National Trust Company of New York City.

Big Railroad Deal in Connecticut.

A dispatch from New Haven on the 21st inst. says that the trolley road and electric light syndicate known as the United Gas Improvement Company has made an opening wedge for the biggest electric railroad deal in Connecticut history. It secured an option on the Fair Haven & Westville Railroad, which includes the consolidated street railroad system of New Haven. The option, which covers twenty days, allows the United Gas Improvement Company the right to buy the road at $51 per share. In round numbers the road will cost the syndicate $7,000,000.

For more than a year the syndicate has been striving for an opening toward the acquisition of the road. It is needed, it is said, to obtain control of the entire trolley road system of Connecticut and to eventually perfect a trolley line from New York to Boston.

When the deal for the New Haven lines is consummated the trust will own Connecticut trolley property valued at $100,000,000. President Dolan, of the trust, a Philadelphia capitalist, is very active in completing the deal.

Exports of Electrical Material from New York.

The following are the exports of electrical material from the port of New York, for the week ended December 19:

Antwerp, 38 packages, $737; Amsterdam, 2 packages, $10; Australia, 15 packages, $1,014; Barcelona, 13 packages $1,230; Brazil, 24 packages $913; British East Indies, 8 cases, $302; Bristol, 1 case, $104; Central America, 49 packages, $3,056; Cuba, 28 packages, $599; Dutch East Indies, 2 cases, $57; Dutch West Indies, 3 packages, $76; Geneva, 85 packages, $910; Genoa, 335 packages, $29,098; Glasgow, 7,654 packages electrical cables and supplies, $16,084; 53 packages, $9,451; Hamburg, 27 packages, $3,031; Havre, 37 packages, $297; 1 case motors, $4,075; 27 cases, $10,000; Hong-Kong, 95 packages, $12,247; Japan, 81 packages, $9,621; 29 cases, $10,472; 37 packages motors, $4,849, Korea, 9 cases, $524; 14 packages, $6,440; Liverpool, 74 cases, $11,556; London, 343 packages, $24,195; 5 locomobiles, $1,250; Manchester, 47 packages, $7,300; Marseilles, 11 packages., $1,652; Mexico, 31 packages, $655; Milan, 3 cases, $200; Naples, 38, cases, $600; Newcastle, 22 packages, $2,000; New Zealand, 7 packages, $75; Philippines, 73 packages, $8,160; Santo Domingo, 236 packages, $1,541; Southampton, 69 packages, $4,397; St. Petersburg, 1 package, $150; Tasmania, 5 cases, $26; Venezuela, 54 cases, $3,761.

PERSONAL MENTION.

Mr. Homer Anderson, electrician of Peekskill, N. Y., has received a communication from F. E. Drake, Director of Machinery and Electricity at the Paris Exposition from the United States, informing Mr. Anderson that his exhibit of hand electro-magnet winders received an honorable mention.

Mr. D. H. Louderbach, who represented Charles T. Yerkes in the purchase of the franchise for running an electric underground railroad in London, returned to this city last week.

Mr. B. P. Gay, postmaster of Smithfield, Va., recently began his duties as secretary-treasurer of the Isle of Wight Telegraph & Telephone Company, succeeding J. Waverly Thomas.

INCORPORATIONS.

The F. L. Smith Electric Company, Harvard, Ill.—to furnish light, heat and power. Capital stock, $10,000. Incorporators: F. L. Smith, E. B. Smith and L. H. Smith, all of Harvard.

The Thorntown Electric Light Company, Thorntown, Ind.—to manufacture and generate electricity. Capital stock, $15,000. Incorporators: A. N. Hodgen, R. A. Asche, R. Bamberger, all of Thorntown.

The Sierra Electric Power Company, Pierre, S. D. Capital stock, $750,000. Incorporators: Anthony P. Morris, Hiram G. Tarr and T. P. Estes.

The Marine Manufacturing Company, Camden, N. J.—to deal in electrical and mechanical engineers. Capital stock, $200,000. Incorporators: R. C. Ellis, E. F. Glenn and R. I. McKinstry.

The Monticello, Fallsburg & Wahite Lake Railroad Company, Monticello, N. Y.—to construct and operate electric railroads. Capital stock, $250,000: Incorporators: T. R. Du Bois, J. C. McGuire, F. X. Keiling, J. L. Sommer, all of Newark, N. J.; J. H. Wanamaker, Brooklyn; C. M. Fuller, Jeffersonville; L. Hausser, Harrison, N. J.; J. R. McParlan, New York City, and J. C. Terbell, Liberty.

The Citizens' Gas & Electric Company, Council Bluffs, Ia.—to do a general gas and electric light business. Capital stock, $150,000. Incorporators: C. W. Perkins, E. J. Dudley, L. B. Dailey, K. K. McLaren, L. A. Kapebyea and H. W. Meen, all of Jersey City, N. J.

The Dubinski Electric Works, San Antonio, Tex. Capital stock, $5,000. Incorporators: L. Kaufman, Ed Noagelin and M. Milgrom.

The Boyce Ice Water & Electric Power Company, Jersey City, N. J.—to deal in ice and electric power. Capital stock, $100,000. Incorporators: R. M. Wiers and I. C. Edgcomb, both of Jersey City.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 18, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

664,096. Electric-Railway System. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Oct. 31, 1900.

ELECTRIC LIGHTS AND APPLIANCES.

663,981, Electric-Lighting Appliance. Arthur Peters, Manitou, Col. Filed Nov. 11, 1899.

664,083. Clutch for Electric-Arc Lamps. Charles E. Harthan, Lynn, Mass., assignor to the General Electric Company of New York. Filed March 10, 1899.

664,209. Electric-Arc Lamp. James A Brennan, Worcester, Mass. Filed Sept. 11, 1897.

664,222. Cover or Shade for Incandescent Lamps. William R. Krumwiede, Providence, R. I. Filed March 1, 1900.

ELECTRICAL MACHINERY AND APPARATUS.

664,061. Electric Switch. Charles W. Scott, Lynchburg, Va. Filed Aug. 16, 1900.

664,077. Operating Dynamo-Electric Machines. William L. R. Emmet, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed June 29, 1900.

664,080. Motor-Switch. Henry Geisenhoner, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed May 4, 1899.

664,086. Regulator for Electrically-Actuated Air-Compressors. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York Filed Nov. 7, 1898.

664,087. Automatic Rheostat. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Nov. 7, 1898.

664,092. Electricity-Meter. William M. Mordey and Guy C. Fricker, London, Eng. Filed Oct. 10, 1900.

664,190. Alternating-Current Electric Motor. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed Aug. 19, 1897.

664,191. Call-Register or Service-Meter Circuit for Switchboard Apparatus. George K. Thompson, Malden, Mass., assignor to the American Bell Telephone Company, Boston, Mass. Filed Oct. 8, 1900.

664,195. Controller-Switch. Noble Vance. Chicago, Ill., assignor to the Hewitt Lindstrom Motor Company, same place. Filed July 23, 1900.

664,247. Dynamo-Electric Machine. Justus B. Entz, Philadelphia, Pa., assignor of one-half to Guy F. Greenwood, Allegheny, Pa. Filed Nov. 27, 1897.

664,265. Electric Meter. Edward S. Halsey, Chicago, Ill. Filed July 5, 1900.

TELEPHONES AND TELEPHONE APPARATUS.

663,998. Germ-Destroyer for Telephone-Mouthpieces. Lewis L. Lacey, Austin, Tex. Filed April 20, 1900.

664,346. Telephone-Call Register. William H. Barker, Hartford, Conn., assignor to the Gray Telephone Pay Station Company, same place. Filed Aug. 10, 1898.

MISCELLANEOUS.

663,859. Receiver for Printing-Telegraphs. John Burry New York City. Filed Aug. 18, 1896.

663,903. Telegraphic Instrument. Harry T. Johnson, Jersey City, N. J. Filed Feb. 26, 1900.

663,926. Auxiliary Attachment for Signal-Boxes. Bartholomew Oehmen, New York City, assignor to the Gamewell Fire Alarm Telegraph Company, same place. Filed May 22, 1900.

663,929. System for Heating Conductors of the Second Class. Carl D. Raab, Kaiserslautern, Germany. Filed April 30, 1900.

663,937. Primary Battery. Charles B. Schoenmehl, Waterbury, Conn., assignor to the Waterbury Battery Company, same place. Filed Feb. 27, 1900.

663,938-664,006-664,007-664,008. Galvanic Battery. Charles B. Schoenmehl, Waterbury, Conn., assignor to the Waterbury Battery Company, same place. Filed March 22, 1900, June 12, 1900, Aug. 21, 1900.

663,951. System of Motor Control. Albert H. Armstrong, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Oct. 6, 1900.

664,004. Electrical Piano. Stephen K. Reynolds, New York City, assignor of one half to Frank W. Chamberlin, same place. Filed June 10, 1899. Renewed May 17, 1900.

664,023. Electric Accumulator. Pascal Marino, Brussels, Belgium. Filed June 23, 1899.

664,046. System of Non-Interchangeable Contact Parts. Rudolf Hundhausen, Wilmersdorf, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Nov. 4, 1899.

664,081. Electrical Heating Apparatus. Carl Gohlin, New York City. Filed July 26, 1900.

664,105-664,106. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Feb. 20, 1900, Aug. 30, 1900.

664,135. Electric Sweeper and Dust-Gatherer. Corinne Dufour, Savannah, Ga. Filed July 31, 1900.

664,144. Electrical Connection. William Gerhardt, Hazleton, Pa. Filed Sept. 27, 1900.

664,163. Combined Automatic Gas-Light Extinguisher and Electric Sparker. Gustav H. Lippmann, Milwaukee, Wis. Filed March 20. 1900.

664,176. Electric Insulator. Emil Risler, Freiburg, Germany. Filed July 25, 1900.

664,189. Electrical-Switch Cap. George B. Thomas, Hartford, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed Aug. 27, 1900.

664,198. Secondary Battery. Frank W. Wetherill, Philadelphia, Pa., assignor of three-fourths to William S. Kirk and W. Stokes Kirk, same place. Filed Feb. 4, 1899.

664,219. Commutator. Fritz Kaeferle, Hanover, Germany. Filed Sept. 15, 1900.

664,301. Insulator. Richard H. Sterling, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company, same place. Filed March 14, 1900.

664,308. Electrotherapeutic Spectacles. Thomas B. Zeller, Pittsburg, Pa., assignor of one-half to Franklin B. Saylor, same place. Filed Oct. 29, 1900.

664,334. Manufacture of Carbid of Calcium. John M. Morehead, Chicago, Ill., assignor to the Union Carbide Company, same place. Filed Dec. 12, 1899.

664,348. Electric Clock. Ulysses L. Collins, St. Louis, Mo. Filed Nov. 20, 1899.

664,360. Igniter for Gas or Oil Engines. Albert T. Otto, New York City. Original application filed Dec. 26, 1896. Divided and this application filed May 19, 1899.

664,362. Galvanic Battery. Eason L. Slocum, Pawtucket, R. I. Filed March 7, 1896.

664,366. Fire-Alarm-Telegraph Box. Leonidas G. Woolley, Kenton, O., assignor to the National Magneto Electric Telegraph Company, Springfield, O. Filed Dec. 28, 1899.

664,367, Electric-Circuit Indicator. Leonidas G. Woolley, Kenton, O., assignor to the National Magneto Electric Telegraph Company, Springfield, O. Filed Dec. 28, 1899.

THE TELEPHONE WORLD.

Bell Telephone Company Wins $12,000,000 Suit.

Justice Colt, in the United States Circuit Court of Boston, Mass., on December 21, decided in favor of the American Bell Telephone Company in the royalty suit brought by the Western Union Telegraph Company.

The case is known as the Stock Ticket Case. The Western Union sought to recoover $12,000,000 royalties under a contract between it and the National Bell Telephone Company, the defendant's predecessor, made on November 10, 1879.

The case has been before the courts since 1883, and was based upon a claim of 20 per cent. of the profits received by the defendant in return for the telephone business of the Western Union Company.

It is stated that the New England Telephone & Telegraph Company has not yet been able to get its lines repaired from the damage caused by the recent storm in some sections of Vermont. The systems are, of course, in good working order, except through new wires and new connections, and it may be weeks before the lines that were damaged, and in many cases destroyed, can be repaired. In Rutland where the greatest damage in that State was done, the trouble has been mostly repaired. In some places the ice around the wires had a circumference of 4 or 5 inches, and this immense weight broke down the poles to such an extent that the lines will have to be rebuilt for several miles in different places. At Newport, N. H., the trouble was worse than at Rutland and the ice still holds the wires there, while at Rutland it has dropped away. It will require several weeks and cost several thousand dollars to make good the damage.

City Attorney Pollard, of Richmond, Va., recently served a notice on the city council that he would, on the second Monday in January, file a petition before the United States Supreme Court to either send back to the United States Circuit Court of Appeals at Richmond the case of the city of Richmond vs. the Southern Bell Telephone Company to force the company to get off the city's streets, or to affirm the decision of the lower court, which was against the company. The case has been in litigation several years, and the lower court decided against the company. If the lower court decision is affirmed the city council will take steps at once to remove all the poles and wires of the company from the streets.

Two new telephone lines from Express, Ore., into the interior will be in operation shortly. The Pacific States Telephone Company is building a branch line from Express to the Gold Hill mines, a distance of six miles. The poles are about all up, and wires are strung from this end of the line. Construction of a private line through Burnt River Valley for the benefit of the ranchers is in progress. Five have already secured service, and every rancher in the valley is taking an interest in the system, and will likely become patrons.

Telephoning without wires was successfully accomplished in Minneapolis, Minn., recently, by transmitting the voice across the Mississippi River near the Franklin avenue bridge, a distance of over 1,000 feet—one and fifty feet of copper wire was strung in parallel lines on either side of the river. The first experiment was tried with five volts. Words could be as distinctly understood as over the regulation wire telephone. Other batteries were then attached, five at a time, finally cutting in twenty volts on one end of the line, with five on the other. The operator at the five end could not only understand what was being said to him, but could hear others talking on the bank of the river near the transmitter.

O. H. Harrell has brought suit against the Northwestern Telephone Company in St. Paul for $50,000 damages. He was in a hole 9 feet deep, in obedience to orders, when the side caved in almost completely burying him. He alleges that he received injuries which will permanently disable him.

The school committee of Somerville, Mass., lately voted to install a telephone system, connecting the different school buildings with the superintendent's office.

The Forman, N. D., Telephone Company has raised its rates to $2 per month for 'phones in business houses, and as a consequence considerable dissatisfaction is expressed by patrons.

The telephone lines of Richmond, Ky., have been purchased by the Cumberland Telephone Company, and made a part of the system.

Independent Franchise Considered in Michigan.

In view of the increasing restrictions upon the use of the telephones in Detroit the members of the common council ommittee on franchises are exhibiting a disposition to most seriously consider the propositions of J. W. Martin, who recently made a request in the council for a franchise for an independent system. Chairman Smith of the committee, Aldermen Beamer, Marx and Lemke, who are particularly incensed at the attitude of the Bell Company, and Alderman-elect Weber, at the invitation of Martin, recently made a trip of inspection to Pontiac, Mich., where a 700-subscriber exchange has just been completed.

"There is every reason," said Mr. Smith, "why the matter of a new telephone company should be prominently and seriously brought before the public. Martin has a good proposition and I am convinced he is able to carry it out. Of course we must protect the city from the possibility of a consolidation if a new company is authorized in the field, but I am assured that there are ways to prevent a repetition of such a consolidation of interests as has come to pass between the Bell and the Detroit Companies. I propose to determine just how this can be done, if this is a fact, and then bring Martin's proposition squarely before the council."

Mr. Smith, it is said, is in receipt of hundreds of letters from citizens of Detroit and outside towns reciting grievances against the Bell combination and urging the council to give a new franchise to anybody who exhibits a serious intention of alleviating the present unbearable conditions.

Independent Company Wins in Ohio.

The city council of Alliance, O., at a recent special session passed an ordinance granting a franchise to the Stark County Telephone Company, a branch of the United States Telephone Company. This is looked upon as the end of the bitter war that for ten months has been waged between the Bell and independent companies in the effort of the former to keep the latter from gaining a footing there.

Three different franchises were knocked out on technicalities by the council and the courts.

At a recent meeting af the directors of the Weakley County Telephone Company of Martin, Tenn., R. W. Martin and J. M. Gardner were appointed supervisors of the entire system, which embraces four exchanges—Martin, Dresden, Gleason and Mt. Pelia, Tenn. A number of changes have been made in the system, one of which was installing a new switchboard at Dresden, which is working nicely. The list of subscribers is constantly increasing, there being nearly 200 in Martin. The company has a bright prospect for much success in the future.

The Missouri & Kansas Telephone Company announces a cut in rates, effective January 1. The Churchill-Craddock Company of St. Louis, Mo., is putting in a system there, and is expected to be ready for business the first of the year, hence the cut. The rate has heretofore been $3 for business houses and $2.50 for residences per month. In future the rate to residences will be $1.50.

E. L. Bailey, of the Dundee, N. Y., Electric Light Company, has completed a telephone line between Dundee village and the hamlets of Starkey and Eddytown, N. Y. The line will prove to be a great convenience. Mr. Bailey is preparing to establish a telephone exchange in Dundee, and expects to secure all the business places and a goodly portion of the residences.

W. H. G. Butler, for several years past manager and chief stockholder of the Citizens' Telephone Company at Columbus, Ind., a branch of the Harrison Company, has sold his stock to S. P. Sheerin, of Indianapolis, and will move to some point in Illinois and establish a local company. Max Hosea, chief lineman, will succeed him as manager.

From Glenwood Springs, Col., comes the information that the Colorado Telephone Company has connected up its line, making a complete circuit from Denver, Leadville, Aspen, Glenwood, Grand Junction, Montrose, Ouray and Silverton, Col., with all the intermediate points. This means a circuit of over 500 miles.

The Newark, O., Independent Telephone Company, which recently secured connection with the new exchange at Columbus, has arranged to connect with 172 miles of toll lines in Muskingum, Holmes and Coshocton Counties of that State, and the exchanges at Frazeysburg, Warsaw and Bloomfield.

The Hatboro, Pa., borough council has passed an ordinance permitting the Interstate Telephone Company to erect wires in the town.

'Phone Company of Massachusetts Open for Business.

The Massachusetts Telephone Company has completed practically all the preliminary work incidental to the opening of an independent telephone service in Boston and last week commenced as an operating company. The cables have been completed and connected, the switchboard set up and the operators engaged to answer the calls of 6,000 subscribers. The main office of the company, at No. 185 Franklin street, Boston, was lately put in touch with its subscribers within a block of the old New England Telephone Building in Franklin street, and hardly more than that from the present building of the American Bell Telephone Company, or as it now is called the American Telephone, Telegraph & Cable Company.

The new company occupies two floors. The lower floor is for the executive offices, which are nicely fitted, and upstairs is the main operating room. The management has secured the lease of the upper floor for the convenience of the operators.

The switchboard, built by the Stromberg-Carlson Company, has a capacity of 1,800 lines. The Stromberg-Carlson central battery system, which is used, does away with the necessity for batteries at the subscribers, end of the line, all of the batteries being in the main office.

Direct connection is made with the cables and ducts.

The company now covers the business and financial centers of Boston, over 800 miles of copper wire having been laid, and the ducts are in every street in the business center and are capable of enlargement.

Long-distance telephonic communication between this city and Philadelphia was resumed last Friday. There was a break in the service Thursday night, and searchers who went looking for the causes of the trouble found that thieves had cut and carried away whole sections of the valuable copper wire, near Linden, N. J. A section from pole to pole is worth between $60 and $80. The country about Linden is sparsely inhabited, and the thieves worked undisturbed. It is believed the thieves who stole the wire are also responsible for similar thefts in near-by towns.

John I. Sabin, president of the Pacific States Telephone Company of San Francisco, Cal., has sent a letter to Mayor Phelan, in which he threatens to remove, on December 31, 1900, all the telephones now used by the city government unless the bill for the month of November is paid. Supervisor McCarthy's agitation against paying the demands, claiming that the company owes the city for license taxes on nickel telephones, resulted in it being held up by the finance committee.

There are nearly 3,000 telephones in use in Tacoma, Wash., an increase of more than 1,000 since last January.

A telephone line from Huntington to Burns, Ore., is projected.

TELEPHONE INCORPORATIONS.

The Brazil Telephone Company, Brazil, Ind.—to operate telephone lines Capital stock, $10,000. Incorporators: A. P. Markle, F. D. Blue, P. S. Markle, all of Brazil.

The United States Telegraph & Telephone Company, Philadelphia, Pa. Capital stock, $2,000,000.

The Northern Indiana & Southern Michigan Telegraph Company, Lagrange, Ind.—to establish telephone and telegraph lines. Capital stock, $20,000. Incorporators: A. J. Hostetter, R. Ellison, A. H. Ellison, all of Lagrange.

The Mt. Pulaski Telephone & Electric Company, Mt. Pulaski, Ill,—to furnish light, heat and power. Capital stock, $5,000. Incorporators: J. W. Collins, H. S. Bakemeyer, O. M. Hubbard, all of Mt. Pulaski.

The Central Energy Telephone Company, Frankfort, Ind. —to operate telephone, lines. Capital stock, $30,000. Incorporators: J. H. Murphy, M. W. Hopkins, W. Payne, all of Indianapolis.

The Northwestern Telephone & Telegraph Company, Dover, Del.—to construct and operate telephone lines. Capital stock, $200,000. Incorporators: C. E. Milligan, A. E. Killey, E. O. Humphrey, E. L. Granel, all of Carthage, N. Y.; E. A. Laughlin, G. J. Atkins, both of Chicago, Ill.

The Harrison County Telephone Company, Cadiz, O.—to construct and operate telephone lines. Capital stock, $25,000. Incorporators: A. J. Vernier, C. O. Juvenal, J. M Schrieber, W. W. Wright, W. W. Potts, R. Cunningham.

The Farmers' Mutual Telephone Association, Mechanicsburg, O.—to operate a telephone system. Capital stock, $10,000. Incorporators: H. C. Rogers, D. J. Burnham, E. W. Patrick, A. F. Burnham, O. R. Hinton and C. W. Martin.

GENERAL ELECTRICAL NEWS.

Lighting.

Beaver Falls, Pa.—The College Hill borough has voted to give the council power to borrow $12,000 for an electric light plant.

Blair, Wis.—The citizens have raised a fund of $2,000 to be used in putting in an electric light plant. W. G. Hyslop is at the head of the movement.

Bonham, Tex.—M. Watson of this place contemplates installing an electric light plant in the near future.

Butler, Pa.—Application will be made to the Governor on January 8 for the charter of the Schuylkill Light, Heat & Power Company to supply electric light, heat and power to the residents of Butler Township. The charter members of the company are Chas. P. Donnelly, Arthur W. Ormerod, T. D. Pitts, W. B. Griffiths and Harry B. Davis.

Chicago, Ill.—The Government is to erect an electric lighting plant at Fort Sheridan military post. A. G. McPherson of Highland Park has been engaged to prepare the plans and specifications for it.

Chickasha, I. T.—A charter was lately granted the Chickasha Water & Electric Light Company to put in a plant at this place. The capital stock is $250,000 and the incorporators are A. J. Campbell, H. B. Johnson and E. Blake.

Cottage Grove, Ore.—This city will install an electric light plant.

Ellsworth, Wis.—E. S. Willey and E. Buck have purchased the electric light plant here and it will be improved extensively.

Fairbury, Neb.—This town is negotiating for an electric light plant.

Galena, Ill.—About $18,000 will be expended on the new electric lighting plant here.

Hartington, Neb.—There is talk of purchasing an electric light plant for this place.

Knightstown, Ind.—This city is preparing to own and operate its own electric light plant in the near future.

Mangum, Okla.—Moore Mill & Gin Company of this place wants information and estimates on an electric light plant for a town of 1,200 population.

Milwaukee, Wis.—The North Milwaukee Electric Light Company has been incorporated by A. D. Meiselbach, Otto Brandis and John H. Hurley, to take charge of the electric lighting business in that village. The capital stock is $15,000.

Minneapolis, Minn.—A change in the method of computing charges for electric light in this city has been announced, which amounts to a reduction of 33⅓ per cent. to people who use their lights longer than one hour a day.

Nashville, Tenn.—This city will want bids next spring on a plant of 400 2,000 candle power arc and 5,000 incandescent lamps to cost not more than $150,000. Address J. M. Head, mayor.

Norman, Okla.—At the next meeting of the city council Hon. J. C. Walls and F. Essex will make a proposition to put in an electric light plant.

Oquawka, Ill.—The Oquawka Button Company is thinking of putting in an electric light plant.

Philadelphia, Pa.—The director of public safety has announced the award of the bids for public electric lighting for 1901 to the Brush Electric Company.

Pittsfield, Ill.—There is talk of a new incandescent electric light plant in this city. Local capitalists are figuring on organizing a stock company to put in an entirely new outfit.

Richmond, O.—The contract for the new municipal electric light plant here will be let January 3, and the construction of the same will be commenced at once.

Saybrook, Ill.—The citizens of this place contemplate the erection of an electric light plant.

Scranton, Miss.—J. Summersgill of this place wants a small electric light plant complete.

Southboro, Mass.—This place is to have electric lights in the near future.

Springfield, Mass.—The Hill shops of the armory are soon to be equipped with a new and larger dynamo for the purpose of lighting the grounds and all the buildings with electricity. With the exception of the milling department, all the Hill shops are now equipped with electric light.

Stamford, Conn.—The citizens here are contemplating the erection of a municipal electric lighting plant.

Stella, Neb.—A stock company has been organized among the local business men for the purpose of establishing an electric light plant.

Tiskilwa, Ill.—The citizens here are agitating the question of erecting an electric light plant.

Trenton, N. J.—Articles of consolidation were filed last week merging several electric light companies in the northern part of this State into the Central Electric Company, whose capital stock is increased from $100,000 to $750,000.

Two Rivers, Wis.—J. P. Miller has applied to the city council for a franchise to erect an electric light plant here.

Warren, Ill.—Plans are being formulated to erect an electric light plant in this town, to cost about $10,000.

Waterbury, Conn.—The citizens of this place have decided to take steps to petition the Legislature for permission to bond the city to the amount of $100,000 for the purpose of going into the business of municipal electric lighting.

White Pigeon, Mich.—The citizens of this place want electric street lights and a company of promoters is desirous of establishing a plant to furnish such service, but as yet the two have been unable to agree on the price.

Street Railways.

Beaver Falls, Pa.—The route of the new electric street railway, connecting this place with New Castle, was recently gone over by J. C. Whitta and Dr. T. P. Sampson of Beaver Falls. Work will be begun on the building of the new line early in the spring, and contracts for material are now being made.

Chattanooga, Tenn.—C. P. King and J. H. Jeffries, of Philadelphia, have been here to reorganize three rapid transit companies in which they have invested largely. The new company will control electric lines to Chickamauga Park, 10 miles from this city, to all suburbs at the base of Mission Ridge, to the heights north of Chattanooga, across the Tennessee River.

Dover, Del.—Delaware's State capital will soon be connected with Wilmington, Del., and Philadelphia by trolley.

Elkton, Md.—It has been decided to construct at once the proposed electric road in Cecil County between here and Chesapeake City. The cost will be $126,400, and the length about eight miles.

Greencastle, Ind.—The county commissioners have granted a franchise to W. B. Vestal and others to operate electric lines on the principal thoroughfares in Putnam County. It is probable that an east and west line will be built within a short time.

High Point, N. C.—The Winston Electric Company contemplates extending the line from Winston and Waughtown to this place. Applications for a charter for such extension will be made to the next General Assembly.

La Porte, Ind.—L. B. Bradley, representing Chicago capitalists, was granted a franchise here for the immediate construction of an electric railroad to connect La Porte and Michigan City.

Litchfield, Ill.—O. W. Atterbury of this place, proposes to build an electric road from here to Hillsboro. The Montgomery County board has granted a franchise.

Manchester, Va.—Capitalist Townsend of St. Louis, Mo., backed by St. Louis capital, has completed plans to construct an electric line between here and Petersburg, a distance of 21 miles.

Natchez, Miss.—The Natchez Electric Street Railway & Power Company has been chartered with $150,000 capital stock by A. G. Campbell, Capt. J. W. Lambert and T. Reber.

Newburgh, N. Y.—There is a movement on foot to have a trolley road run from here to connect with the New Paltz road.

Norfolk, Va.—The Bay Shore Company is being organized by H. L. Page to build an electric line from this city to Ocean View.

Paw Paw, Mich.—The Kalamazoo Valley Traction Company has been granted a franchise for an electric railway through this village. The proposed road will be part of an electric system from Detroit to Benton Harbor. Attorney Palmer of Detroit, is working up the matter on behalf of the company.

Pittsburg, Pa.—It is reported that a deal will be closed to-day at the office of the McKeesport & Youghiogheny Traction Company in this city, in which 100 towns, taking in 600,000 people, will be brought into closer touch with each other. The line will be 118 miles in length and will furnish direct communication between Pittsburg, Uniontown and Connellsville.

Rome, Ga.—The proposed extension of the city electric railway to Lindale will be about five miles in length and it is estimated will cost $25,000.

Smyrna, Del.—The project of running a trolley line down the State from Delaware City via Odessa, through Thoroughfare Neck to this place is again revived. Harry A. Richardson, Peter J. Ford, Peter L. Cooper and others are the promoters of the scheme.

Sullivan, Ind.—The commissioners of this place are considering applications for electric railway franchises covering 200 miles.

Manufacturing.

Chicago, Ill.—The General Pneumatic Company of this city has recently been formed with a capital of $25,000 for the purpose of manufacturing power, electricity, vehicles, motors, etc. Peter W. Thede, Frederick Gehn and Thomas P. Kerrigan are all interested in the concern.

Garwood, Pa.—The American Machinery & Export Company of this place was lately incorporated in Trenton, N. J., and will manufacture railroad, electric light and telephone equipments on a capital of $250,000. E. A. Simmons, W. B. Smith, both of Garwood; J. P. Powers, of Elizabeth, are among the interested parties.

Syracuse, N. Y.—The Crouse-Hinds Company, manufacturers of electrical supplies, will remove to new quarters on Jefferson street about January 1. Considerable new machinery will be purchased when the building is ready for the occupancy.

Wilmington, Del.—A large order has been closed with the Sprague Electric Company for 20 horse power motors of the slow speed direct connected type to operate the new plant of the Delaware Button Company in this city.—The Clarke Electro Company was organized here last week, for the purpose of manufacturing and dealing in medical electrical appliances.

Company Matters.

Cleveland, O.—The plant of the Brown Hoisting & Conveying Company and that of the Elwell-Parker Electric Company, were totally destroyed by fire last week, with a loss of nearly $1,000,000.

Pittsburg, Pa.—The contract for the wiring and electric fixtures for the new Union station has been awarded by the Pennsylvania Railroad Company to Carter & Fullman of this city for about $50,000.

Automobiles.

New Albany, Ind.—The Louisville Automobile Cab Company of this place will operate a cab and transfer service.

Newark, N. J.—The Thompson Automobile Company filed articles of incorporation with the county clerk lately. The purpose is set forth to be the manufacture of all kinds of automobiles. The capitalization is placed at $250,000. The principal office of the company will be at 810 Broad street, this city. J. C. Bleveney and C. F. McGuire, of this city, and J. S. W. Thompson, of Morristown, are named as incorporators.

Wilkes-Barre, Pa.—The electric busses have proven such a success that the company has ordered three others for use in various parts of the town. Posten Brothers also have one that they use between the depots and the hotels.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The Chicago Union Traction Company has passed the dividend on its preferred stock for the quarter.

The United Telegraph & Telephone Company, Philadelphia, was incorporated at Dover, Del., on December 21 with a capital stock of $2,000,000.

The Boston Electric Light Company has declared a regular quarterly dividend of 2 per cent., payable January 15 to stockholders of record January 1.

It is reported from Chicago that the Union Traction Company of that city is earning at the rate of about 4 per cent. on the first preferred stock.

The Amalgamated Copper Company's dividend is payable January 28 to stockholders of record December 27. Books close December 27 and reopen January 29.

A special meeting of stockholders of the Westinghouse Electric & Manufacturing Company has been called for February 20, to act on a proposition to increase its capital stock.

The directors of the General Electric Company have declared the regular semi-annual preferred stock dividend of $3.50 per share, payable January 31 to stock of record at the close of business January 15.

The American Telephone and Telegraph Company has declared the regular quarterly dividend of 1½ per cent. and an extra dividend of ¾ per cent., payable January 15. Books close December 31 and reopen January 16.

Under the call of the United Electric Securities Company of Boston for proposals to sell a sufficient amount of collateral trust 5s to absorb $39,489 there were received $2,000 of the fifth series, $3,000 of the sixth series, and $2,000 of the ninth series, in all $7,000. The average price paid was 103 and accrued interest.

Advices from Houghton, Mich., state that the Calumet and Hecla mine has made a large reduction in its force during the past 90 days, the cuts affecting mills and sundry surface work as well as the mines. Local estimates of 1,200 to 1,500 men out are probably too high, but it seems likely that the force has been reduced by nearly 1,000 men.

At a meeting of the executive committee of the Erie Telegraph & Telephone Company and the Michigan and Wisconsin Telephone Companies in Boston on December 19 it was voted to recommend to the directors that a regular quarterly dividend of 1¼ per cent. be declared by the Erie and Michigan Companies and a dividend of 1¾ per cent. be declared by the Wisconsin Telephone Company, all payable January 14 to stock of record December 31. Books close December 31 and reopen January 14.

The activity and advance in the Massachusetts Electric Companies' common stock, says the Boston "News Bureau," is the result of the contemplated issue of $2,700,000 4½ per cent. five year notes. The issue of these notes and the sale of the Nashua Company stock places the Massachusetts Electric Companies in a position to pay off its floating debt and brings the common stock within sight of dividends, as this plan obviates the necessity of keeping such a large cash reserve. A dividend on Massachusetts Electric common stock in 1901 is regarded as a certainty.

There is considerable apathy apparent in the copper market, though values undergo little open change. It is a fact, nevertheless, that the inclination to purchase copper has abated to a noticeable degree, and manufacturers are in a fair enough position to pull through the balance of the year on their present engagements. Advices report a slacking off among the valley mills, and full active operations are therefore not expected until after the holidays. Stock-taking will occupy a good share of the manufacturers' attention between now and January. A busy year and a firm copper market are expected in 1901.

The report of the Brooklyn Rapid Transit Company for November shows another decrease in operating expenses. The gross income of this property is a well assured quantity, but the operating ratio must necessarily be reduced in order to show a net income for the stock. Extraordinary expenditures which were made at this time last year have been cut down very largely, this perhaps accounting for the decrease in cost of operation of $15,746. Gross earnings increased $2,141, making an increase in net of $17,887. For the five months ended November 30 the gross earnings increased $213,215, while the net income increased $449,985.

The Metropolitan Street Railway Company of New York offers to existing shareholders the right to subscribe to $7,000,000 par value of unissued authorized capital stock at the price of $160 per share. Stockholders are limited to 7-45 of their present holdings as shown on the records on December 26. The money obtained from this stock issue will be used in paying off the floating debt of the company, which accumulated from the construction expenses of the past year, for the changing of motive power on some of the lines of the company to underground electricity. Subscriptions will have to be accompanied by checks for $60 per share, the remaining $100 to be paid on or before January 30, 1901.

Announcement was made on December 20, of the signing of the recently reputed contract between the Consolidated Railway Electric Lighting and Equipment Company, of New York City, and Vickers' Sons & Maxim, of London, whereby the former company's sytem for car lighting by electricity is to be introduced among the railways of Europe. Isaac L. Rice, president of the Consolidated Company, has been abroad since last July, arranging to dispose of the company's foreign rights. He has now made a contract with Vickers' Sons & Maxim covering a period of twenty-five years, which will give the latter firm a monopoly of the business. The contract, it is said, is most advantageous to the Consolidated Company.

EDITORIAL NOTES.

The Proposed National Standardizing Bureau.

At the last session of Congress a bill was introduced looking to the establishment of a national standardizing bureau, by means of which accurate scientific methods may be introduced into manufacturing processes and accurate standards and standard measuring apparatus adopted. Such a bureau, as will readily be inferred, would prove invaluable to the electrical industry, which at present has to rely more or less on the apparatus and standards perfected in college laboratories or devised in the experimental rooms of one or two of the large manufacturing companies. Such a method of procedure naturally tends to a wide difference in so-called standard methods and apparatus, resulting in financial loss and frequently in much needless and costly litigation.

Last year the National Electric Light Association adopted a resolution favoring the passage of the bill, but the latter was pigeon-holed for the time being. This important question has again been brought up at the present session of Congress, and only recently the New York Electrical Society passed the following resolutions:

Whereas, It is proposed to establish a national standardizing bureau; and

Whereas, Such a bureau would be of the greatest value and benefit to electrical science and industry in the United States, and assist in the further development of export electrical trade; be it

Resolved, That the New York Electrical Society expresses its approval of the legislation in furtherance of such an object, and

Resolved, That the Society associate itself with kindred bodies to secure the establishment of the bureau.

In view of the interest taken in this measure by the principal electrical organizations in this country, due to the benefits that would accrue to the trade in general and to the export trade in particular, it is to be hoped that the bill will speedily become a law and that the first year of the new century will see this Government equipped with a national standardization bureau equal to that of other countries, for it is a well-known fact that the extensive scientific work carried on in the laboratories of the different departments of the Government requires the use of many standards and instruments of precision which cannot be procured or tested in this country, thus involving a loss of time, inconvenience and lack of uniformity.

* * *

Exports of Electrical Apparatus.

In this the first issue of ELECTRICITY of the new century it might be in place to review in a general way what has been accomplished during 1900—at least so far as the statistics have been compiled—in the way of electrical exports from the United States to other countries. That our electrical export business has grown materially is clearly shown in the fact that the electrical goods shipped from the port of New York alone to Great Britain for the week ending December 19, 1900, amounted to $59,135 as against $9,325 to the same country for the week ending December 23, 1899. Further, the total amount of electrical goods shipped from this port to all parts of the world for the week ending December 19, 1900, amounted in round numbers to $200,000 as compared with $100,000 for the week ending December 23, 1899.

During 1899 there were comparatively few electrical goods shipped from this country to Cuba and the Philippines, whereas during 1900 scarcely a week has passed that several thousand dollars' worth has not gone out to these islands.

In fact such a creditable record has been made in the export business by the electrical industry during the first ten months of 1900—the exports of electrical machinery during that period reaching a total valuation of $4,555,015 as against a value of $2,454,510 for the same period of 1899, while those of instruments and apparatus for scientific puposes, including telegraph, telephone and other electric devices, amounted in value to $5,401,365 during the ten months of 1900, as compared with a value of $4,642,994 for the same period of the preceding year—that no opportunity should be allowed to pass which promises enlargement or widen ing of that business. These figures are interesting and instructive as showing how rapidly our electrical export trade is growing in strength and scope, but even the enormous trade, as shown above, is no fair indication of what is to come. The figures already quoted make it apparent that our electrical manufacturers have taken up the extension of their foreign trade in earnest, and unless all signs fail the result of their efforts will be manifest

Digitized by Google

in the creation of a foreign business that will stand out prominently in the record of exports compiled each month by the Treasury Department.

* * *

The Lighting of Railway Trains. At the International Railway Congress at Paris two interesting reports were presented upon the subject of train lighting, covering the methods now and previously in vogue on the Continent of Europe and in Great Britain. The reports, according to the "Railway Age," cover the early methods of lighting by oil, with the statement of its advantages and defects, but the portion of the papers of special interest in the comparison made of the relative merits of gas and electric lighting—including under the former head, gas from petroleum and other mineral oils, pure acetylene, and gas mixed with acetylene, and under the latter head, electric lighting from storage batteries alone, and from storage batteries in connection with dynamos. Among other things, M. Chaperon, of the Paris Lyons & Mediterranean Railway, and M. Herard, of the Orleans Railway, in their report say:

"In gas lighting the cost of installation for the manufacture and supply of the gas is quite considerable. The expense for labor is reduced to the minimum, the services of the staff being limited to wiping the cups and chimneys of the lamps, the examination of the burners and supplying the reserves or tanks of the carriages. The advantages of the system are principally in the quality of the lights, the facility of modifying the intensity as well as the simplicity of the labor in maintenance and cleaning, and in the activity in filling the supply tanks.

"Electric lighting is, without contradiction, that which is presented under the most attractive form. Incandescent electric lamps have, in fact, an incontestable superiority over all the other methods of lighting, as much from the point of view of comfort as that of facility of installation of luminous centers, which may be as intense as desired, and which can be placed at the most convenient points for the passengers. They produce no, or next to no heat, and there is no occasion to provide for the products of combustion being carried outside. The electric lighting of the carriages produced by means of a dynamo driven by the axle during the run of the train realizes, in principle, a complete and rational system of lighting."

The second report, by M. Cajetan Banovits, considers at more length the dangers arising from liability to fire and explosion in the case of gas lighting, which he conceives to be much greater than in the case of oil lighting, and finds in this the excuse for the many Continental railway companies which cling to oil lighting for at least trains of the second order. In his final observations, M. Banovits says:

"In fact, it cannot be concealed that between the methods of lighting by candle and oil on the one side, and electric ligting and mixed gas lighting on the other, the difference is immense. The luminous intensity which has been secured (and which may yet be surpassed by these two last methods of lighting) is such that it unites perfectly all the requirements; and finally electricity presents a complete security against dangers of fire and explosion."

M. Banovits sums up as follows:

"Of all the modes of lighting adopted up to the present time for the lighting of trains, that which seems to us to answer the best to the conditions of a perfect light is electric lighting, for, besides offering the greatest security against the danger of fire, it possesses a proper luminous intensity, assures a light, clean, fixed, exempt from atmospheric influences, and permits a simple and economical dimming for the night. This mode of lighting has, moreover, the advantage of a simple maintenance, and, as soon as its application is made upon a large scale, a service will be assured by proper installations, which will be regular and rapid, even in cases of the densest train movement. Everything in short, invites to the belief that, from the pecuniary point of view, this method of lighting will permit more favorable economical results than have hitherto been attained; and under this head it may pertinently be remarked that the advantages which at the moment other methods of lighting may appear to present over electric lighting are largely offset by the superiority of safety conditions and by the other inherent advantages of the method."

As our contemporary, already referred to ates it is to be regretted that the methods of train lighting in vogue in the United States were not touched upon. The car axle lighting system as made use of on the Santa Fé road, and to a limited extent elsewhere, would seem to be rapidly reaching a state of perfection, both for economy and safety, and it would therefore have been interesting to have heard the French experts' opinion on the system.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Frankfurter "Zeitung" says that the Nuremburg Electric Company has started the manufacture of electric typesetters. This is a new departure in Germany.

A patent was issued in this country on December 25 to Anton Pollak of Buda Pesth on a telautograph, for which the inventor makes the following claim: In a fac-simile telegraph, the combination of a vibrating member, a mirror receiving a ray of light from said member, and moving it across a surface, means for moving said mirror at one rate of speed, and means for moving said mirror to a position where it can again move said ray of light across said surface, said last-named means acting to move said mirror at a greater speed than said first-named means.

Mr. Alfred C. Harmsworth, proprietor of the London "Daily Mail," who arrived in this country on December 27, referring to the outlook for American brains and machinery in England, is reported as saying: "You have a big chance now with automobiles. We shall shortly be spending $500,000,000 converting our horse car services to electric; you can get most of that. We must put up two or three times that amount for new suburban surface car systems for our big city. Much of that will go to the immigrant from America."

The lighting of Kimberley, South Africa, by electricity is now a fact. The works have cost $125,000 and comprise among other things two 212 hp. boilers of 110 lbs. steam capacity, supplied by Messrs. Babcock & Wilcox; a 154-tube Green economizer; a Worthington horizontal and a compound vertical feed pump; a 7,000-zinc tube Worthington condenser; a Worthington cooling tower served by a forced draught fan, driven by a 10 hp. motor; two 2,200 hp. engines for driving two direct coupled generators each of 2,500 16 cp. lamp capacity; two 2½ ton overhead tramways for the engine room, and an eight-slab marble switchboard, fitted with 28 instruments. Accumulators are to be provided to afford a night supply of current at an additional outlay of $25,000. The present capacity of the plant is 5,000 16 cp. lamps, but an increase on this it is anticipated will be necessary in the near future.

Nikola Tesla, has been invited by Rear Admiral R. B. Bradford, chief of the Bureau of Equipment, to submit for trial a system of wireless telegraphy which he has developed. Mr. Tesla was in Washington a few days and conferred with Rear Admiral Bradford. He says that he will be able to provide the navy with a system which will be equal, if not superior, to that invented by Signor Marconi. Before finally adopting any special system for the naval service Rear Admiral Bradford proposes to make a thorough investigation of various wireless telegraphy systems in operation.

At a recent meeting of the Liverpool, England, Medical Institution the electromagnet designed by Prof. Haab, of Zürich, Switzerland, for removing small fragments of iron and steel from the eye, was described. Various speakers gave instances of the success of this magnet. It requires about 1¼ kw. to energize it, and is capable of lifting about half a ton.

A representative of the General Electric Company is said to be working on a plan to generate electricity by water power and supply the current to the Union Traction Company and the Philadelphia Electric Company. If the scheme proves to be practical it is said that the United Gas Improvement Company will undertake the enterprise.

A barge canal, costing $62,000,000, following closely the Erie Canal, State Engineer Bond will recommend to the Legislature February 12. Minute details will be given. Electricity may be recommended for motive power. Lieut.-Gov. Wooodruff is positive the recommendations will be agreed to by the Legislature. Then it will go before the people next fall. Mr. Woodruff believes the Legislature should sit until the question is decided.

Consul Roosevelt, in a report to the State Department from Brussels, says that the company which was organized there in 1898 to establish electric traction on navigable ways in Belgium closed its books for the first time on June 30 of last year with a balance of more than $5,074. The company has devoted nearly all its time since its organization to erecting buildings and putting in machinery. Electric traction was first put into operation by the company between Virginal and Ruysbroeck, a distance of 13,669 miles. He says: "Eleven communes have already contracted with the company for public lighting for a period of 30 years, and other communes are negotiating for the same purpose. The company has recently submitted to the Government proposals for

Digitized by Google

lighting 11 railway stations between Brussels and Charleroi. The managers believe that before the ending of the third fiscal year their contracts will embrace 10,000 lamps, which, estimated at 15 francs ($2.89) per lamp, will represent an annual revenue of 150,000 francs ($28,-950.) Negotiations are now going on for supplying 240 horse power from 10 to 20 hours per day. From this branch of the enterprise the company calculates upon an annual income of at least 125,000 francs ($24,125). It is equipped to supply electricity for towing by day and night, for small and medium industries, and eventually for vicinal rail and tramway lines and night public lightning.

MODERN electric fire engines are now used in Paris, Tex.

THE Great Dog Falls, over which the drainage of 1,200 square miles of territory passes, are to be developed into electrical power and the power transmitted to Port Arthur, Ont., by wire. The company which will develop the power has been quietly investigating the possibilities of these immense falls. The Ontario Government will be interviewed with the object of securing control of the falls at once. The Great Dog Falls are in an air line about 25 miles from Port Arthur, and according to estimates, are capable of giving 5,000 horse power the year round.

IN the State Archives at Rome it has been found that the X-rays may successfully exhibit the writing on manuscripts concealed in old book covers whenever this writing is done in red lead, ultramarine blue or cinnabar. They are being used also in attempts to detect forgeries of paintings and in efforts to discover signatures of old masters in paintings alleged to have been produced by them.

AN official report shows that the water plant owned and operated by the municipality of Paris netted a profit of 15,000,000 francs ($3,000,-000) during 1900; a small municipal electric light plant, started as an experiment two years ago, cleared 900,000 francs ($180,000).

A SCIENTIST in Vienna, Austria-Hungary claims to have discovered that a very moderate current of electricity will sterilize milk by destroying all the bacteria in it.

THE already practically foreshadowed widening use of aluminum conductors for electric transmission purposes adds interest to Lord Kelvin's recently expressed opinion of them, says "Cassier's Magazine." The weight of aluminum required, he said, is almost exactly one-half of the copper which would produce the same effect. The diameter of cable is 28 per cent. in excess of one made of copper, and the cost of insulation for an underground cable is increased in about the same proportion when we pass from copper to aluminum. Aluminum is not a pleasant metal to deal with, but its high conductivity will make it invaluable for overhead transmission. It is true also that the weight to be supported on posts is half of copper, but the surface exposed to the wind is greater, and its strength is not great. The chief drawback to its use, especially overhead, is its liability to become rotten. This defect does not exist if the metal be pure, and especially if free from sodium. But exposure to the atmosphere, especially near the sea, induces deterioration. The fact that aluminum is easily oxidized ought not to condemn it. The same is true of iron and steel, and yet we do not hesitate to place structures of these metals in exposed positions. Only we paint them; so Lord Kelvin proposes that we paint or varnish aluminum conductors wherever necessary. A few hundred yards of 1¼-inch aluminum wire were put up by Lord Kelvin on a Scotch estate somewhat over a year ago, and on this line he is watching the effects of the weather.

WITH the passing of the solitary Back Bay horse car, but one species of that style of conveyance is left in Massachusetts, and, indeed, in New England. When electricity became a factor in transportation the West End Company of Boston was not slow to recognize its power. In 1888 the overhead system of electric propulsion was inaugurated on the Back Bay cars. From its inception electricity spread over the lines of the West End Company almost too rapidly for people to understand its merit. With the inception of electricity the horse as a motive power was a mark for relegation. So rapid has been the pace of electricity that the little railway at Onset Bay on Cape Cod stands alone as a horse-propelled corporation.

THE Canadian Pacific is contracting for 2,000 horse-power for its road between Rossland and Robson, B.C. It seems that for steep grades and circuitous routes electricity is better than steam. For one thing there is less haulage on account of the source of the power. That is to say, it is not necessary to employ a heavy locomotive, the use of which alone consumes a great deal of energy. If electricity will serve in the mountains it ought to be of even greater economic advantage in a flat country.

LIEUT-COL. CROMPTON, who commanded the Volunteer Electrical Engineer Corps of Royal Engineers during the disturbance in South Africa, has returned to England from Pretoria, and tells some wonderful tales of the manner in which electricity was made use of. The telegraph and telephone wires were constantly in use, and the electric arc lamps threw a bright light on the veldt at points where Boers had wrecked lines or blown up bridges. The khaki cycle was in daily use by the engineers, who plied to and fro repairing wires cut by wily Boers. The traction engines were utilized to work the dynamos which enabled searchlights to sweep the veldt in search of retreating foes, and in this and many other ways electricity was made to play an important part in the war.

THERE has been a tremendous increase in the use of electricity for lighting purposes in New York City during the past year. One of the big electric lighting companies estimates the growth of its own service at from 30 to 50 per cent. or from 1,000,000 or 1,200,000 lamps to 1,400,000 or 1,500,000. A considerable part of this increase is due to the introduction of electricity into new dwellings and apartment houses, but the equipment of the new buildings of several large department stores has also helped to swell it.

A COMBINATION of the Edison and Boston Electric Light Companies of the city of Boston is said to be likely. Circulars calling a meeting of the stockholders of each corporation were recently mailed. The meetings will be held within a fortnight. Each company pays 8 per cent. dividends and earns a great deal more. The new plan is to eliminate competition, and to enable the stockholders to receive large surplus earnings. J. Pierpont Morgan is the largest stockholder in the Edison concern, and it is he who is credited with arranging the details of the proposed consolidation. Very few of the stockholders know anything of the plan. A few, however, have had an inkling of what is coming, and have bought all the stocks of each company that have been offered for several weeks, steadily advancing the quotations. The details of the plan are being kept secret.

IN regard to alterations reported to be contemplated at the Berlin, Conn., electric station of the New York New Haven and Hartford Railroad Company, Superintendent Davidson, of the Hartford division, said a short time ago that, while the third rail system would no doubt be extended, he did not think the changes to be made at Berlin would mean the enlargement of the system at present. Eventually, he said, however, the third rail system would be extended to the line between Berlin and Middletown, Conn.

SOME 900,000 miles of electric wire were in use for telephony in the United States in 1899, with 1,000,000 telephone instruments and 400,000 stations. It is estimated that the capital employed in this industry in the United States approximates $100,000,000. The telephones of the whole world are estimated to number $1,500,-000, with 1,750,000 miles of wire. The telephone service in this country thus approximately equals that of all other countries combined. In 1876 there were 200 instruments working in Europe and 380 in the United States.

HOW wonderfully advanced Japan is in practical applications of electricity may be gathered from a brief survey published in the "Zeitschrift für Elektrotechnik," which reports amongst other information, that the Japanese Government has sanctioned important railway extensions in the island. A number of new full-gauge lines, including a 20 mile stretch between Osaka and Kobe, and two other stretches having lengths of 18 and 13 miles respectively, some of which are already in course of construction, will be equipped for electric traction. An extension of the network of street railways connecting Tokio and the principal factories with the more important seaports is also proposed—this to be likewise equipped for electric traction. It is stated that Japan already possesses upwards of 400 electric generating stations, of which 19 serve solely to supply energy for working street, mine, and factory railways, while the remainder supply energy to towns and villages for lighting purposes, and to factories, etc., for both power and lighting purposes. General supply stations having an individual output of 4,000 hp. and upwards exist in Tokio, Kobe, Nagoya, Yokohama, and elsewhere. The motive power is supplied in each of these cases by steam.

WE are in receipt of a generous sized box of varied colored pencils from the Joseph Dixon Crucible Company of Jersey City, for which we herewith tender our thanks. Pencils are always acceptable to a newspaper office—all the more so in this case owing to the fine quality of the plumbago.

"Electricity's" Educational Series.

BY R. MAX EATON.

ARTICLE NO. 8.

COILS AND COIL MAKING.

It would be practically impossible to give in one article a full treatise on the subject named, a subject on which volumes have been written, however we will endeavor to give you as clear as possible an explanation of the laws governing the action in different styles of coils, the application of which we will encounter further along in the series.

We might say here that the application of coils is so varied both in purposes and results that it would be out of the question to attempt individual description of the classes, but the laws governing them and their action is what we will try to explain, and it is then left to the electrical student to design the apparatus to suit the conditions or to understand the governing influences of the apparatus in action.

In most coils you will notice that very soft fine iron wire is used for the core. The reason that this is done instead of using a solid piece of iron is as follows:

First—It more readily conforms to the influencing condition.

Second—It is susceptible of a more intense magnetic condition.

Third—To prevent eddy currents. Eddy currents are induced in all closed circuits or masses of metal which are in the influence of a varying magnetic condition. This is productive of heat and causes a loss of power.

It has been proven by experiment that any change in the magnetic field surrounding a wire tends to set up an electric current in the wire, just the same as a change in an electric current which flows in a wire causes a corresponding change in the magnetic condition surrounding it.

A current of electricity flowing in a circuit will induce a current in a parallel circuit as long as the magnetic condition surrounding the first, or inducing conductor, is kept in motion.

Lines of force, whether radiating from a conductor over which a current is flowing or from a magnet, will induce electrical action in a conductor, within its influence, as long as the magnetic condition is kept in motion. Also if the conductor be put in motion and the magnetic condition remain stationary, the same results will follow. A result will be accomplished so long as either one or both be in motion.

When a current is made (started) in a circuit its magnetic lines commencing at zero circle outward and will induce electrical action in a parallel conductor in just the opposite direction to the flow in the primary or inducing circuit.

When a current is broken (stopped) in a circuit the magnetic lines will decrease in strength, circling inward toward zero point and induce electrical action in a parallel conductor in the same direction as the flow in the primary or inducing circuit.

The induced electrical action only exists while the magnetic lines are in motion, which occurs only when the primary current is disturbed.

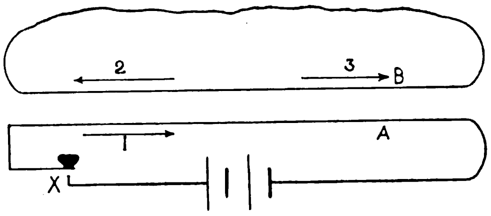

FIG. 1.

In Fig. 1 if a current be started in the circuit A by closing the key X then the magnetic lines will circle outward cutting the parallel conductor B and inducing in it a current in the opposite direction to that flowing in A or as indicated by the arrows 1 and 2.

If the key X be opened, breaking the circuit, then the lines of force will circle toward their center or vanishing point, and in doing so will cut the parallel conductor B in just the opposite direction that they did before and induce in it a current in just the opposite direction to that first induced, which will be in the same direction as the inducing current, indicated by arrow 3.

If the primary circuit be wound as a coil on an iron core, the lines of force will be collected and the acting magnetic condition thereby intensified, producing greater results in a parallel winding which is wound over the primary circuit.

The coil which contains no other source of electrical action than that received by induction is called the secondary. The coil in which the original or inducing current flows is called the primary.

The magnetic condition produced by a primary coil besides acting on a secondary or separate coil will also act upon itself, and why not? The law of induction says that current flowing will induce action in a parallel conductor, and is not every turn and layer in a coil parallel with itself? Then action will be set up within itself by its own influence just the same as in the secondary, and this condition is called the law of self-induction. When a current is started in a coil and the lines of force cut the turns of the coil in their outward path, it induces in them an electric pressure which opposes the growth of the current. On opening the original current the magnetic field quickly dies away and the lines of force again cut the turns of the coil, but this time in such a direction that the self-induced pressure upholds the original current.

This effect of self-induction is made use of in a number of ways, one of which is the ordinary gas lighting coil, which is simply a coil containing many turns of insulated wire wound on a core of iron wire. Let us follow out the law in this coil as an example.

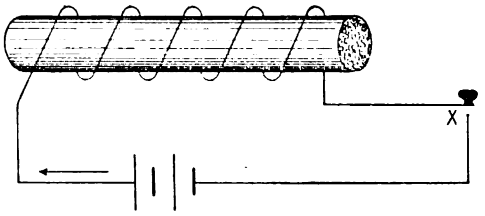

FIG. 2.

In Fig. 2 when a current is passed through the coil by closing the key X the core becomes magnetized and the lines of force radiating from its poles cut the turns of wire in the coil as it increases, which tends to set up a flow in the coil in the opposite direction to the original current. When the magnetism has reached its full value and remains so the induced action stops.

Now break the circuit at the key X and you will discover that quite an intense spark will be given out across the contacts during the break. This is caused by the lines of force decreasing in strength and cutting the turns of wire on their inward path, causing an induced action in just the same direction as the original flow, or in other words, helping it so that the original current plus the induced action causes the intense spark which is the result secured by the gas-lighting coil.

In summing up the conditions encountered in coils we find the following laws governing their action, which must be taken into consideration in their construction and in the object to be attained by their application.

When a circuit is made or a flow of current increased the induced action is always in the opposite direction.

When a circuit is broken or the flow of current decreased the induced action is always in the same direction.

No induced effect will be attained unless the primary or inducing current is being made and broken or else when the rate of flow is being varied.

The induced action in a secondary coil causes a magnetic field which opposes the growth of the primary magnetic field when the circuit is made and opposes the decay of it when the circuit is broken.

When electric currents are induced by a changing magnetic field, the magnetic field belonging to the induced current tends to stop the change in the original field.

The varying of the magnetic field of a coil will act upon its own windings, tending to retard both the increase and decrease of the flow, which is called the law of self induction.

A flow of current does not necessarily have to be made and broken to cause induced action; varying the rate of flow in any degree will produce an effect.

These laws, as given above, are the governing influences which determine and control the action of all such coils as electro-magnets, induction coils, spark coils, retardation coils, impedance coils, transformers, solenoid coils, repeating coils, etc.

Of course these coils will all come up for explanation later on in the series when we come to their application, but we would respectfully ask the student to thoroughly digest this article, for on these laws depend nine-tenths of the electrical phenomena of to-day, and as we come to the application the action and part performed by these coils will be readily seen and clearly understood.

Article No. 9 will be entitled "The Principle of the Dynamo."

Will Use American Machinery.

Electricity is conquering the world with greater rapidity than did its mighty predecessor in mechanical achievement, steam. The gradual opening of the trans-Siberian Railroad has led to the introduction of electric light and electric machinery into the towns of Siberia. Recently the municipality of Vladivostok resolved to build at once about 20 miles of electric tramways, and to light the town with electricity. Most of the machinery will be of American manufacture.

LIQUID FUEL.*

BY E. L. ORDE.

The early history of liquid fuel has been so ably put before this Institution by the late Mr. B. G. Nichol and later in the admirable paper of Mr. Wallis, that there is no need today to recapitulate what has been done up to the present time with this form of combustible. The writer, however, ventures to think that the practical results of some experiments with which he was entrusted, and the conclusions to which they have led, may be not without interest to the members of this Institution, and may at all events, form the basis of a profitable and interesting discussion. It is only within the last few years that liquid fuel has come within the province of engineers in this country, owing to the fact that hitherto it has only been practically obtainable in the vicinity of the Caspian Sea at such a price as renders it commercially possible. Within the last few years, however, a considerable change has taken place. New oil fields have been discovered, and the number of places along the eastern route at which liquid fuel can be obtained has increased so enormously that it becomes a serious question for shipowners to consider whether it is not an absolute economy to use it in preference to coal on vessels trading to the eastward. The solution of this question lies first in the cost of the fuel and its practical calorific value as compared with coal. Secondly, in its effect on the life of the boiler furnaces in which it is burnt, and thirdly, perhaps the most important of all, its immunity from danger. The first point is, of course, constantly varying, and is one which the writer is not in a position to pursue. The two latter practically resolve themselves into one—the efficient combustion of the fuel. The existing appliances designed for the purpose may be broadly divided into three.

1st. Those in which the liquid fuel is injected into the furnace in the form of a spray by purely mechanical means.

2d. Those in which the spray is produced by the introduction of a gaseous medium, and

3d. Where the liquid fuel is introduced into the furnace in the form of vapor.

Before considering the respective merits of these three classes of apparatus it will be advantageous to realize the actual possibilities of the fuel. The experiments which the writer carried out were made with crude Borneo oil, which is in all respects an excellent fuel oil, and is to be obtained in large quantities. Its composition is:

Carbon........................	87.09 per cent.
Hydrogen.....................	10.78 "
Oxygen........................	1.24 "

The flash point is 211° F.; the boiling point is 395° F. The calorific value determined by the bomb calorimeter is 18,831 B.T.U. It is an exceptionally clean and mobile fuel oil, and with its high-flash point the risk of adventitious explosion is reduced to a minimum. All fuel oils are exceedingly complex, inasmuch as they are made up of a number of combinations of carbon and hydrogen which only a chemist, who has devoted himself to investigating hydrocarbons, can appreciate at their true significance. The importance of this point for the practical purposes of the engineer lies in the fact that the various constituents of the fuel give off vapor at temperatures varying from about 100° F., up to the boiling point of the oil, and when the boiling point is approached —unless special precautions are taken—a residue of solid carbon is formed which will soon choke any pipes or narrow passages through which the fuel may have to pass. Having thus considered the characteristics of a typical fuel oil, we may now return to the consideration of the apparatus for burning it.

In the first type—the purely mechanical spray —the oil is discharged under pressure into what is commonly called a burner, which is made of such a form that the effluent jet is broken up into particles sufficiently small to burn readily at the firing point of the fuel. The full efficiency of the system can only be obtained by lining the furnace with firebricks, or other non-conducting material, so as to raise the furnace temperature (by preventing the absorption of the heat into the boiler) until it is sufficiently high to vaporize the greater portion of the oil before it is burned. The quantity of air required to complete combustion is very largely in excess of what is chemically necessary, and the furnace space required for oxidation is large. The advantages of the system are: First, its simplicity; and secondly, its noiselessness. As regards efficiency, the best results that the writer has been able to find recorded show an evaporative efficiency of about 12.5 lbs. of water from and at 212° per pound of oil. With Borneo oil this gives a fuel efficiency of 64.6 per cent. In the second class the oil is introduced into the furnace in the form of a spray in the presence of a gaseous medium—be it steam or air. In most of these appliances a partial lining of firebrick is fitted in the furnace, and a brick bridge or baffles of various forms are built with a view of obtaining complete oxidation of the fuel. The earliest form of this apparatus consisted simply of two pipes, lying one above the other, and having their ends flattened so as to spread the streams of oil and steam. Oil is admitted to the upper pipe, and is allowed to drop from the orifice into the jet of steam which passes through the lower pipe and meeting the oil breaks it up into particles sufficiently small to ignite as soon as the firing point is reached. This simple device has been improved upon by numbers of engineers, and most of the improved burners of this type take the form of concentric tubes, through which the oil and steam are passed. Adjusting arrangements are always provided, so that the supply of the two elements can be regulated at will. This type is better known than any other, and has, so far, given the best results. The evaporative efficiency of the best burners of this type seems to be about 13-14 lbs. from and at 212°, but the supply of air required for oxidation though smaller than that demanded by the first-class burner is much above what is chemically necessary. The difference between steam and air as spraying media will be touched upon hereafter. The third class of apparatus, that is, in which the fuel oil is wholly or partially vaporized, promises to give the best results.

Attempts have been made so long ago as 1867 to produce an apparatus on the system, and Colonel Foote claimed remarkable results for his method of solving the problem; these results, however, seem not to be well authenticated. Later, Messrs. Dorsett and Blyth attempted to boil the fuel in one boiler and burn the resultant vapor in the furnace of another. This, however, does not seem to have been very successful. Mr. Thwaite has since then made an apparatus consisting of a retort which is maintained at a red-heat, and into the retort a spray of steam and oil is blown; the oil is immediately volatilized and passes through holes in the retort into the furnace, where it is met by a stream of air in which the vapor burns with a clear blue flame. The results are said to be satisfactory, but it is difficult to see how such a process can be carried out with ordinary fuel oils without producing a large deposit of carbon in some form in the retort. An experiment tried by the writer with an apparatus on this principle showed that it was possible to produce a high-furnace temperature and a smokeless fire, but the retort was soon completely choked with solid carbon, or, if the temperature was allowed to fall, with a pitch-like substance. This deposit presents the greatest difficulty in the way of vaporizing so complex a body as the ordinary fuel oil. As has been pointed out before, the oil consists of a number of hydrocarbon combinations, each of which has a different boiling point.

Another important characteristic of these hydrocarbon compounds is that in the presence of superheated steam they can be completely distilled without cracking, and the explanation of this fact (on which depends the Ragosine process for refining petroleum) has been stated to be that in the presence of superheated steam the boiling point, or, more correctly, the mean boiling point, of the oil is lowered. This distillation, however, does not apparently take place with any other medium but steam. To insure distillation it is necessary that the temperature of the oil should be raised to as near the boiling point as possible before it is admitted into the presence of the steam, and it is in this part of the process that the danger of cracking appears. In the apparatus fitted by the firm with which the writer is connected the difficulty has been overcome, and so far as it has been possible to ascertain, by ordinary means, complete vaporization has been secured.

The vapor thus produced can be completely oxidized by the amount of air chemically necessary, and a larger quantity of oil can therefore be treated in the same furnace space than by either of the two other systems, while the combustion as shown by the analysis of the waste gases is complete. Two typical analyses are given below:—

Analysis of waste gases.		Per cent.	Analysis of waste gases.		Per cent.
Carbon dioxide	equals	13.2	Carbon dioxide	equals	12.6
Oxygen	"	3.6	Oxygen	"	4.0
Carbon monoxide	"	0.0	Carbon monoxide	"	0.0
Hydrocarbon gases	"	0.0	Olefines, etc.,	"	0.0
Hydrogen	"	0.0	Hydrogen	"	0.0
Nitrogen	"	83.2	Nitrogen	"	83.4
		100.0			100.0

The only feature calling for remark is the somewhat large percentage of uncombined oxygen, which is no doubt due to leakage around the smokebox. As regards efficiency an evaporation of from 15-16 lbs. from and at 212° should always be obtained with dry Borneo oil.

The hydrocarbon vapor is exceedingly unstable and appears to depend for its existence entirely on temperature. Efforts have been made to collect samples for analysis, but without success. In appearance it is of almost milky whiteness, closely resembling the vapor given off from the retort used in the Pintsch gas system. The smell is pungent, and severe irritation is set up in the membranes of the mouth and throat if the vapor is inhaled. At the temperature of the external air (60°) it was found almost impossible to ignite it, and the outer surface of the jet was at once condensed and formed an oil deposit of a very much lighter

* Paper read before the North East (England) Institution of Engineers and Shipbuilders, Nov. 16, 1900.

Digitized by Google

color than the fuel oil itself. The flame when the vapor is burned in a boiler furnace over a layer of broken firebrick is of dazzling whiteness and becomes almost transparent as it approaches the bridge. The exact form in which the combustion of these hydrocarbon vapors takes place does not seem to be clearly understood. The appearance of the flame at a distance of a few inches from the nozzle of the burner suggests that at that point the hydrocarbons are burning in the form of acetylene. All gaseous hydrocarbons when exposed to a temperature of 1,000° F. become acetylene, and it seems fair to assume that the vapor will do the same. As the flame proceeds further into the furnace, however, and the temperature becomes higher, the hydrocarbon combination must break up and the rest of the vapor is probably burned as carbon monoxide and hydrogen. This theory is put forward with diffidence in the hope that the reaction which takes place may be more worthily dealt with in discussion. There seems to be no doubt that the efficiency of liquid fuel lies in the fact that it is capable of being turned into vapors of high calorific power, and that the vaporizing process does not demand a large heat expenditure.

The two classes of apparatus first described do not vaporize the fuel before combustion begins, which means that of the heat generated in the furnace some considerable part is absorbed for this purpose, and is therefore not available for evaporating water. To attain to the temperatures required for complete vaporization, part, at all events, of the constituents must be exposed to the heat of the furnace, but with careful design the quantity of heat thus abstracted can be reduced considerably below that which is necessary to carry out the process when the fuel is simply injected into the furnace as spray. The fact that superheated steam lowers the boiling point of hydrocarbon oils, and therefore prevents cracking, renders its employment essential if it is desired to burn the fuel as vapor. The objection to using it on board ship is, of course, the loss of fresh water and the amount of heat lost in making this loss good by distilling sea-water; this loss, however, is—the writer ventures to think—more than compensated by the gain in efficiency due to using steam as a distilling agent. Mr. Morison has published some calculations of the quantity of fuel required for distilling purposes and applying these calculations to a steamer with engines indicating 2,000 hp. at sea, the quantity of oil fuel required to make up in the evaporator the water lost in the burners only amounts to one quarter of a ton per day of 24 hours. In this calculation, Mr. Morison's calculated result has been multiplied by four to allow for deposit on the surface of the evaporating coils. With air as a spraying agent, there is, of course, no loss of fresh water, but it is questionable whether the quantity of steam used in the air compressors is not greater than that required in the burners and evaporators together. The complete combustion of petroleum spray depends, firstly, on the correct relation between the volumes of the oil and the spraying agent, and secondly, on the velocity of the spraying agent, both of which requirements place air at a considerable disadvantage as compared with the steam. The general conclusions produced from the investigations the writer has made are as follows:

1. Liquid fuel of good quality, such, for instance, as Borneo oil, used in boiler furnaces, if efficiently treated, should show a reduction in consumption of about 40 per cent. as compared with coal.

2. A reduction in bunker space of about 15 per cent. for the same weight of fuel; a reduction of about 50 per cent. for the same radius of action.

3. A reduction in the stokehold staff of at least 50 per cent.

The advantages of the liquid fuel as regards ease of manipulation, cleanliness, absence of smoke, reduced temperature of stokehold as compared with coal, increased life of boilers owing to constant temperature, improved performance of engines owing to constant steam pressure, need not be enlarged upon to the members of this Institution, but the question of immunity from danger requires some consideration. With a fuel oil of which the flash point is 200°F. or over there should be no risk of explosion whatever, and unless there is want of ordinary care in the management of the burning apparatus and the fuel supply the danger of fire ought not to exist. Still, fires have occurred, and it may be well to consider the causes from which they have originated. The most fruitful cause appears to be intermittent action of the burning apparatus. This may arise from dirt in the oil or from the presence of water. To get rid of the dirt it is only necessary to provide an efficient filtering apparatus and this should form a part of all liquid fuel installations. The second cause, the presence of water, presents a more difficult problem. All crude oils have a certain proportion of water intimately mixed with them, and as the specific gravity of most fuel oils is from 0.9 to 0.98, and in the case of some shale oils even higher, it is obviously exceedingly difficult to eliminate this water by gravitation unless the temperature of the mixture is comparatively high. The expansion of oil under increase of temperature is considerably greater than that of water, and some arrangement whereby heat can be applied to the contents of the bunker seems to be necessary where crude oil is used. In furnaces where the oil fuel is burned in the form of vapor the danger of extinction from the fact that water is present is of course considerably reduced, for any temperature that is sufficiently high to vaporize a fuel is more than sufficiently high to evaporate water, so that when water passes into the apparatus with the oil it flashes into steam, and though it breaks up the stream of hydrocarbon vapor does not prevent each fraction from burning unless the amount of water is abnormally large. An experiment made by the writer showed that the fire was not extinguished when water was present in the proportion of five parts of water to three of oil. The water in this case was added gradually, and the contents of the bunker were constantly stirred so as to secure as complete an admixture of the oil and water as possible. With a burning apparatus of the second type, where the oil fuel is introduced in the form of spray, the danger of extinguishing the fire when water is present is of course much greater, but with a well designed installation and proper care on the part of the attendants such accidents as fires should be impossible.

II.—HIGH TENSION POWER TRANSMISSION PLANTS IN FRANCE.

BY FRANK C. PERKINS.

Monophase and Triphase Plant at Chapareillan-Chambery

The alternating current power transmisson plants as installed by the Société L'Eclairage Electrique of Paris are all equipped with apparatus designed by M. Labour. In each succeeding plant which was built in France by this firm, improvements were made and the power transmission system by alternating currents was in each case proven to be the best means for flexibility, cheapness, economy and satisfactory operation.

FIG. 4—POWER HOUSE AT CHAPAREILLAN, FRANCE.

Gradually the potentials used were increased and success followed each new project. At the Chapareillan-Chambery alternating transmission plant the pressure was first placed at 5,000 volts, but later other machines were installed and the voltage increased to 15,000 volts.

The power house (Fig. 4) of this plant is located in the valley and is situated at a distance of 10 to 12 kilometers from Chambery, where the current is used for lighting and power purposes. The power station is located at the

Digitized by Google

Chapareillan end of the line, is substantially built of stone, and is divided into two parts for turbine room and generator room. In the generator room (Fig. 5) there are two direct connected units, each group having a capacity of 200 hp. The alternators are of the monophase type as first introduced, and later were supplemented by triphase generators. The voltage of the monophase alternators as delivered by the machines is only 110 volts, and is conducted through the switchboards to the transformers. Each alternator is supplied with its own switchboard, furnished with main switches, ammeters, voltmeters, and other measuring instruments for both alternating and direct current for excitation. Step-up static transformers raise the potential to 5,000 volts, which was the potential first used on the line. The three-phase machines supply a polyphase current which is raised in voltage to 15,000 volts.

The latest machines produced by the Société L'Eclairage Electrique generate a current of 30,000 volts direct for the transmission lines. The machines were exhibited by this firm at the World's Exposition just closed at Paris. They created great interest from the fact that by the use of such machines as these it is possible to do away entirely with the step-up static transformers, and the only conversion necessary is by the use of step-down transformers to reduce the high tension line current to a moderate pressure for local distribution. This high-tension alternator has a fixed armature and a revolving field. The insulation of the armature is thus more easily accomplished and practically as high potentials can be generated direct by the alternators as can be produced by means of static transformation.

The speed of the high potential machine shown in Paris was 420 revolutions per minute. The frequency of this machine was 50 periods per second, which is fast becoming a standard frequency for all polyphase machinery at present being built abroad. Much of the American apparatus is still constructed with 60 cycles and 133 cycles, but the tendency is toward a lowering of the number of alternations. While 60 cycles is extensively used in American plants for lighting systems, a frequency as low as 25 cycles is rapidly coming into use for power installations. The use of incandescent lamps on circuits with frequencies as low as 25 cycles has never been considered practicable, but more than 200,000 lamps will be operated by Niagara power at this frequency at the Pan-American Exposition, and this test will give a good opportunity to judge of its adaptability.

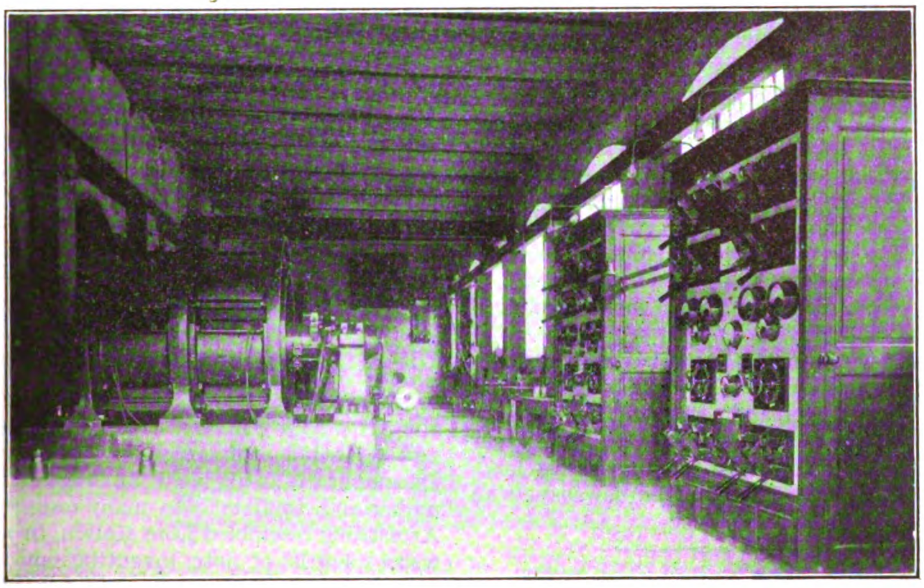

FIG. 5.—GENERATOR ROOM AT CHAPAREILLAN, FRANCE.

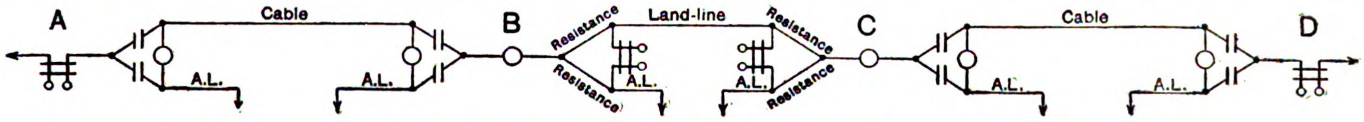
RECORDER WORKING ON COMPOSITE LANDLINE AND CABLE CIRCUITS.*

BY A. DAVIDSON.

The application of Harwood's duplex arrangement to circuits composed of cables and landline, as shown in the accompanying diagram, is, so far as I am aware, novel; and, in view of the extending use of the siphon recorder for landline work, cases may happen where it would be useful. The diagram is almost self-explanatory, and I will only offer a few remarks on the working of the system in practice. B and C are the terminal stations of the landline. The signals from station D, received at C in the usual way, are transmitted direct to station A. Signals from A are similarly transmitted by B to station D. The landline recorders at B and C are permanently in circuit in order to give a record of what is passing through and also to show the state of the balance. If B's recorder is practically unaffected when B is sending to D, while the signals from C to A are of legible size, the same state of things will obtain at A's recorder and duplex working will be possible. The arrangement can be divided up for sectional working by introducing earths at B and C on the apex to apex lead. The principal source of disturbance is, of course, the variation of the insulation of the landline, but the recorders at A and D are so far away electrically that the landline balance must be out very considerably before the incoming signals are affected. I think it will be found, in all cases, that the effect of the cable capacity on the landline balance can be sufficiently compensated by tapping on a large capacity near the end of the landline artificial lines. In many cases this will be unnecessary, and a balance, so far as the distant recorders are concerned, will be obtained by means of a simple resistance. I should point out that the lower the resistance of the landline the better the balance will be. Well-insulated signaling batteries and cable transmitters at B and C are essential. There is no great practical difficulty in maintaining this condition as most stations are (or should be) provided with a direct-reading voltmeter and milliammeter, with which rapid daily tests of the general condition of the batteries can be taken. On a duplex human relay system the arrangement practically amounts to the elimination of one station without introducing any extra contacts or moving parts. I may add that the system has been worked successfully over a tropical landline subject to heavy varying leakage.



*From the "Electrician," London.

Care of Boilers.

Whatever plan is adopted for securing water to feed the boilers should not interfere with the general plan of feeding at the same rate that the steam is used, so that the water line will remain nearly in the same place at all times.

In every plant where there are two or more boilers, it is sometimes necessary to lay off one of them for cleaning or repairs. In fact, every plant should have an extra boiler to use in case of necessity, and this means whenever it is advisable to clean one of them, as the practice of running boilers almost continuously should be discountenanced on all convenient occasions.

The plan of leaving boilers empty is a good one, provided steam and water are excluded from them. This opinion is based on experience in starting up a boiler that had not been used for fourteen years, for no internal corrosion was found in it, while the external parts were but slightly affected by its long rest. It was set in brick according to common practice, two walls of the building serving as a part of the setting. After it had been thoroughly inspected it was run for several years under as much pressure as a new boiler of equal diameter is usually allowed in this vicinity without calling for repairs except tightening two braces, and probably this was needed before it was laid off.

When boilers are to be left idle for a long time they should be thoroughly cleaned as soot collects and holds moisture, so that corrosion goes on underneath the apparently harmless covering until the plates are ruined. A coat of good paint suitable for iron-work will assist greatly in preserving boilers out of use, and as the expense of it is small, it does not pay to neglect it, for good second-hand boilers are frequently wanted by parties who do not care to invest in new ones for reasons of their own; but when corrosion is allowed to eat into the tubes and plates they will soon be fit for the scrap heap only, and are not especially valuable even there.

One advantage of a power pump and a driven well in connection with a good heater is that all of the pumping must be done before the engine is shut down, which means that exhaust

Digitized by Google

steam is passing through the heater, and no cold water can reach the boiler. An injector, says the "Boilermaker," London, is very convenient in such a plant, because it may be run to fill up the boiler after the engine is shut down.

INVENTIONS OF THE CENTURY.

623,535 Patents Granted in the United States in Sixty-two Years.

(From the "New York Sun.")

This has been a century of mechanism. A hundred years ago people were content to live by hand, as it were; now people live chiefly by complicated machinery. Civilized man's mode of existence has been totally altered by his inventions.

The world has gone patent mad. In the United States alone there were 623,535 patents granted in the sixty-two years from 1837 to 1899. During its existence the Patent Office has received more than $40,000,000 in fees. On carriages and wagons more than 20,000 patents have been granted; on stoves and furnaces, 18,000; on lamps, gas fittings, harvesters, boots and shoes and receptacles for storing, 10,000 each. The total of patents for the civilized world is easily twice that of the United States.

With the invention of the steam engine the world shrunk at a bound to a twentieth of its former size. Where the lumbering stagecoach or the plodding caravan took weeks the flying express covers the distance in a few hours. The trip across the Continent used to be a matter of life and death. Now it is a matter of $100 and take your ease as you go. In 1825, the first steam road was opened between Stockton and Darlington, England. A year later a similar experiment was made at Quincy, Mass., where the engine hauled stone for a distance of four miles. The first passenger road in this country was the Baltimore & Ohio, opened in 1830, with a mileage of fourteen miles. To-day, there are 210,906 miles of railroad in this country, 163,216 in Europe, 26,834 in South America, 31,102 in Asia, 9,978 in Africa, and 14,384 in Australasia.

Early in the history of railroading twelve miles an hour was considered recklessly fast. In January, 1899, a train on the Burlington route, in a run from Siding to Arion, 2.4 miles, did the distance in 1 minute and 20 seconds, or at the rate of 108 miles an hour.

Mail communication was as expensive as it was slow in the old days. It cost a shilling to get a letter anywhere, when the century began, and a shilling in those days represented far more than it now does. Now two cents will carry a letter to the Philippines or around the corner. Then the mail matter handled was too insignificant for statistics; now there are 75,000 post offices in this country, handling postal matter of all kinds to a total of 6,576,310,000 pieces.

The first telegraph line in this country was opened in 1844. In 1899 there were 904,633 miles of wire in use in this country; 71,393,150 messages were sent that year.

The year 1800 knew no telephones. A hundred years later sees 772,989 miles of telephone wire in use, connected with 465,180 stations, and answering 1,231,000,000 calls a year. When the century was new it took six weeks to get news from Europe. To-day it takes six seconds. To-day there are 170,950 miles of submarine cable, all laid since the first cable, Field's great achievement, was laid in 1857.

Electricity has come to the aid of steam in traffic. There are more than 1,000 electric street car lines in operation in the United States, with a capitalization of $1,700,000,000. The same electric power, only dimly known before the wonderful century, now lights our cities. In the United States there are half a million arc lights and about twenty million incandescent lights, the latter being equivalent in light-giving capacity of 320,000,000 candle tips such as they used in 1800.

While the railroads have served to diffuse the population from one end of the land to the other, another invention has served to centralize it—the elevator.

In other times they built houses of wood and brick. Now they construct them of steel and iron. And so carefully are the plans developed that the architect can say how many bolts will be required in the construction of a skyscraper, how much each beam can support, where each piece of iron belongs. Wooden bridges have been supplanted by huge steel structures. Even stone towers are being abandoned for the lighter steel. The age of steel is here.

Our vast factory systems employing thousands of workers and furnishing necessaries and luxuries alike at prices that would have amazed the citizen of 1800, have grown out of the substitution of machinery for the hand; the sewing machine, the steam loom, the ring frame, and hundreds of other inventions.

Photography is a product of the last hundred years.

In 1800 the principal daily papers were published in Boston and New York City. The type was hand made and hand set. Nowadays new type is cast while being set; paper comes in rolls from two to four miles long; presses run off 80,000 complete newspapers an hour.

LONDON NOTES.

(From our London Correspondent.)

The Direct Current Arc.

Few papers which have recently been read before the Institution of Electrical Engineers have excited more genuine scientific interest than that read by Mr. W. Duddell on "Rapid Variations in the Current through the Direct Current Arc." Mr. Duddell's previous work and inventions, which were not long ago demonstrated before a similar audience, secured for him an enthusiastic reception. The paper read by him on December 13 on the subject mentioned was illustrated by a most interesting series of experiments, including the use of the arc as a telephonic receiver and transmitter, but his musical arc effects were even more attractive.

Electric Traction vs. Magnetic Observatories.

There are serious indications that electric tramway enterprise in this country is to be hindered so that the magnetic observatories may be spared. For some time a committee has been conferring in London upon the whole subject. The professional element stands up for the observatories, and advocates the continuation of their records uninterrupted by electric tramways or any such thing. The Board of Trade appears to have leanings in the same direction, but the electric traction representatives on this committee strenuously oppose. A most important case has arisen in West London, where the London United Tramways Company's system is ready for running if only the Board of Trade will pass it. But the Board will not do so, and is pressing for insulated return. This, it is represented, would cost the Tramways Company somewhere between $250,000 and $500,000, whereas to remove the Kew Observatory—the cause of the trouble—would perhaps cost $10,000 to $15,000. It was originally intended to have the line worked by double trolley method so as to avoid any trouble, but this provision seems to have been repealed, and the plans, specifications, drawings and so on, all altered, so that after all only a first-class trolley wire system has been laid down. As matters now stand there appears to be a deadlock. If the London United has to give in, the outlook is not promising for other undertakings of a like character.

OBITUARY.

W. H. Moore.

Mr. W. H. Moore died at his home, on West 6th street, Plainfield, N. J., Wednesday, December 26, after an illness of six weeks with typhoid fever. He was 46 years old, and was born in Rahway. He was associated intimately with Mr. Edison, and was largely instrumental in perfecting the incandescent light. He leaves a wife.

Sir William Armstrong.

Lord William George Armstrong, inventor of the Armstrong gun, and writer upon electrical and scientific topics, died on the morning of December 27, at his home at Cragside, Northumberland, England. In many respects Lord Armstrong resembled Lord Kelvin, in that he was a scientist of note, inventing not only the gun which bears his name, but the hydraulic crane and other important devices. Lord Armstrong founded the Elswick Engineering Works in 1847, from which yards many fine ships of war have been turned out. Sir William Armstrong was raised to the peerage in 1887, on the occasion of Queen Victoria's jubilee.

Papers to be Read at the Northwestern Electrical Association Convention

Some of the papers which will be presented at the meeting in Milwaukee on January 16, 17 and 18 of the Northwestern Electrical Association are as follows:

"The Rate Question," by Henry L. Doherty, New York; "Synchronous Converters," by Prof. W. I. Goldsborough, Purdue University; "The Series Incandescent Lighting System of the Future," by P. D. Waggoner, Schenectady, N. Y.; "Practical Line Construction," by Loren W. Burch, Madison, Wis.; "Education of Central Station Employes," by Prof. D. C. Jackson, Wisconsin University.

IT is said that a member of the Automobile Club of America, is writing a playette in which the "auto" will take a prominent part. The time of the play will be A.D 2000 and one of the incidents will be the fright and demoralization of the motor vehicles and chauffeurs by a prehistoric beast called a horse.

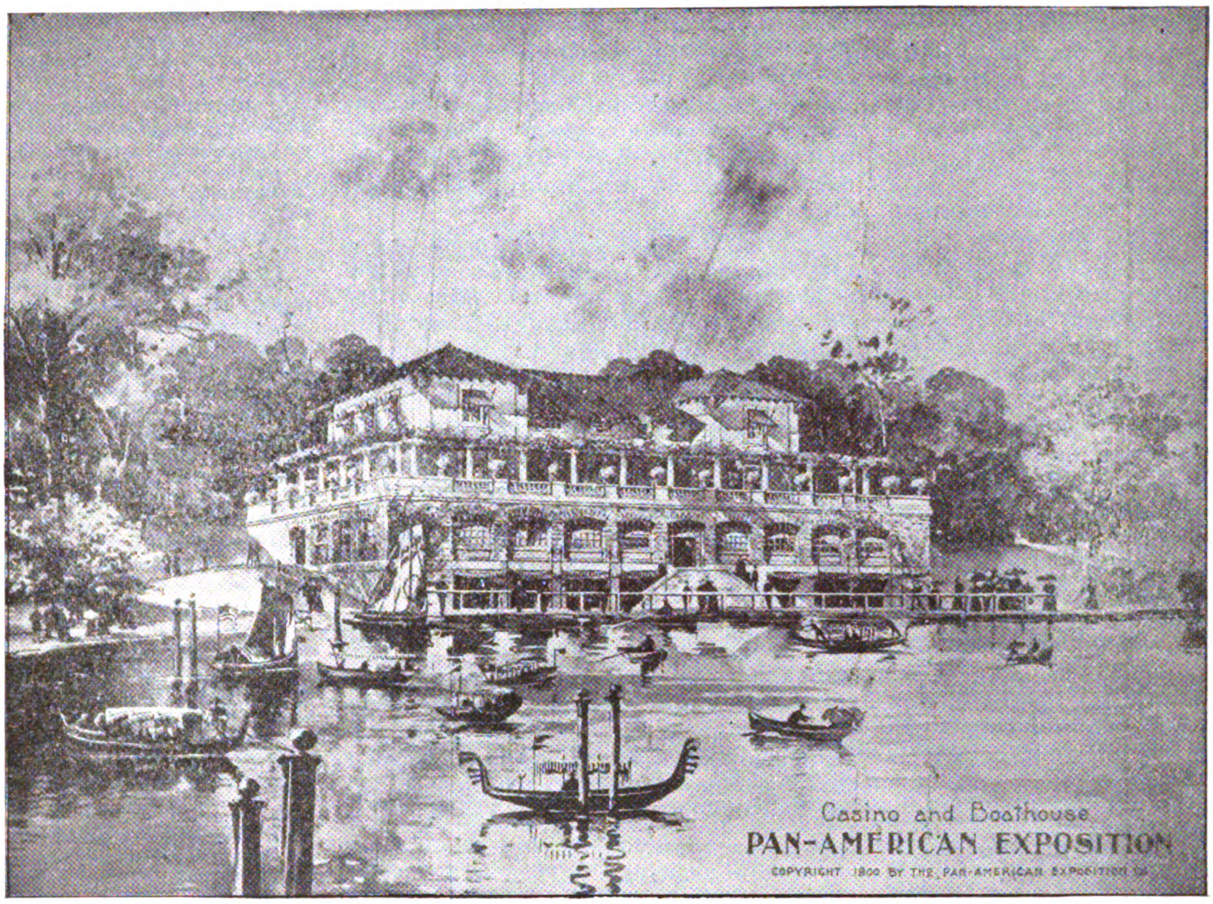
PROMINENT FEATURES OF THE PAN-AMERICAN EXPOSITION.

The Pan-American Exposition at Buffalo may appropriately be termed the "City of Light," as electrical power sufficient to run all the machinery of a large city will be required to illuminate it.

The new Casino and Boat House on the south bank of the Delaware Park Lake, a little to the east of the bridge of the Three Americas, is in a sense a tribute paid to the Pan-American Exposition by the city of Buffalo, though it will be of service for many years after the Exposition has become history. It is a very attractive building, with many conveniences which will be greatly appreciated by visitors.



The first or basement story is built with Buffalo Plains limestone, very rustic in character and decidedly picturesque. In this story will be a restaurant and lounging room. A corridor extends through the entire length of this story of the building, affording ample room for the storage of bicycles and other uses. The basement story will be surmounted by a balustrade of Indiana limestone with turned balusters. Over a large portion of this story will be an open terrace covered by a pergoda. Perhaps the term peristyle would best describe this part of the structure. The columns introduced here are free Doric. The terrace will be of concrete construction with granolithic floors. The building material above the basement story and aside from the terrace will be white bricks, with a roof of rich red Spanish tiles. The second story will be devoted to amusements, and the third story will be occupied as living rooms by the lessee of the building.

Underneath the basement story is the place of storage for boats during the winter, and extending out over the water is a boat platform, 128 feet long and 22 feet wide.

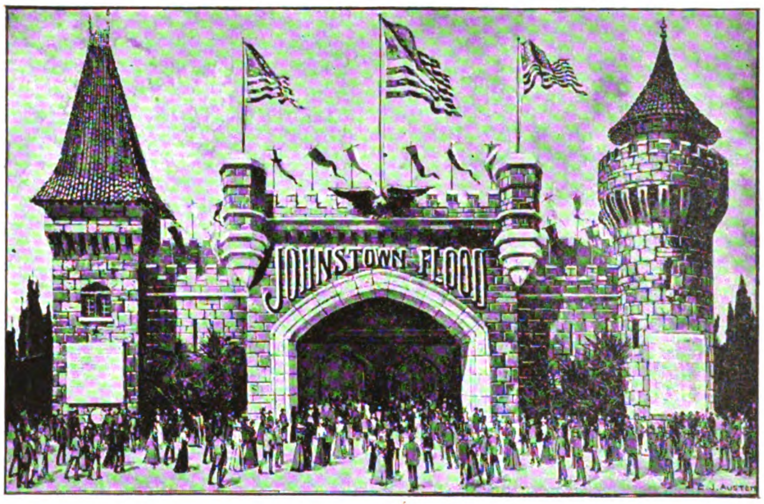
The building covers an area of 109 by 73 feet. its cost is $30,000.

The most vivid scenes of the Johnstown Flood, the accounts of which at the time of the appalling catastrophe electrified the entire civilized world, will be presented in a startlingly realistic manner by means of the scenograph at the Pan-American Exposition at Buffalo next summer. The descriptions of eye witnesses have been followed faithfully by the artist in the portrayal of the scenes. The presentation like the experience of the survivors of the flood is never to be forgotten by those who witness it.

The artistic features of this exhibit have been marked out by Mr. Edward J. Austen, of Newark, N. J., who has had much experience and success, with cycloramic and scenographic productions. Mr. Austen also painted "Niagara-in-Winter," which created a furore in London several years ago.

The scenograph, or living picture, differs from anything of the kind ever used for spectacular productions, and in this respect the presentation of the scenes of the Johnstown Flood will be unique.

The curtain rises upon the city of Johnstown as it was before the devastating flood. It is the even-tide, and the streets are alive with people wending their homeward ways. A passenger train of the Pennsylvania Railroad, in the foreground, dashes past. The sun sinks behind the western hills, and as the shadows envelop the town the lights begin to appear in the windows of the houses. The stars begin to twinkle, and anon the silvery moon sheds her soft radiance abroad. Furnaces and coke ovens in the distance light up the heavens, giving a



startling spectacular effect. A trolley car mounts the hill to the south. The lights in the houses disappear and the city sleeps. The sun rises over the hill-tops and throws its long bars across the scene. Johnstown is again active. Gradually clouds gather in the sky, and

some rain begins to fall, slowly at first, then in torrents, accompanied by thunder and lightning. Suddenly the great dam at South Fork, up the Little Connemaugh, to the east, breaks with tremendous force against it and the water rushes down upon the town, carrying everything before it. The citizens are taken by surprise and many are drowned in the raging torrent. The flood stops at the stone bridge, when the debris piles up and holds the water back. The darkness grows more dense, and soon fire adds its horrors to the scene. All this is brought out very effectively by the scenograph. Finally the scene changes, and the Johnstown of to-day is shown, a busy, thriving town.

Postponed Meeting of the American Institute of Electrical Engineers

The 149th meeting of the A. I. E. E. has been postponed, by direction of the Committee on Papers and Meetings, to Wednesday, January 9, 1901, when it will be held in connection with an Institute dinner at Muschenheim's, 41 West 31st street, at 7 o'clock P. M. The topic for discussion after dinner will be "Electricity in the Last Century and in This." Several eminent members of the Institute will speak upon this subject. The price fixed for dinner is $2.50 per cover.

The council will meet at the office of the Institute at 3 P. M., on the same date.

Applications have been received from the following candidates, which will be acted upon January 25, 1901:

Ermine John Thompson, Pittsfield, Mass.

Charles Tripler Child, Warren Day Brown New York City.

Horace Dowie, Brooklyn, N. Y.

William Edgar Haskins, Worcester, Mass.

Robert Howes, Spokane, Wash.

Carl Price Barnett, Kansas City, Mo.

Harry Philips Davis, Maurice Neville Blakemore, Harve Reed Stuart, Pittsburg Pa.

Henry John Gille, St. Paul, Minn.

Exports of Electrical Material from New York.

The following are the exports of electrical material, from the port of New York, for the week ended December 26:

Antwerp, 181 packages, $9,759; Amsterdam, 7 packages, $274; Athens, 4 packages, $10; Argentine Republic, 211 cases, $6,916; Bilbao, 23 cases, $717; Bremen, 1 case, $200; 4 packages, $69; Brazil, 363 packages, $14,194; 10 packages electrical railroad material, $1,102; Birkenhead 2 cases, $462; British Possessions in Africa, 107 cases, $9,021; British Guiana, 35 cases, $1,270; British West Indies, 91 cases, $2,910; Central America, 130 packages, $1,666; 2 cases, $255; Chili, 1 case, $14; Cuba, 79 packages, $2,548; 4 cases, $760; Ecuador, 33 packages, $796; Glasgow, 102 cable reels, $42,667; 6 cases, $164; 122 packages, $34,236; Hamburg, 105 cases, $11,993. Havre, 81 cases, $11,874; Hayti, 3 packages, $61; Liverpool, $108 packages, $10,131; London, 268 packages, $21,857; Mexico, 4 cases, $355; Newfoundland, 15 cases, $443; Newcastle, 45 cases, $5,400; Nova Scotia, 11 cases, $124; Peru, 79 packages, $3,375; Portuguese Possessions in Africa, 31 packages, $2,185; Porto Rico, 14 packages, $942; Southampton, 51 cases, $3,153; St. Petersburg, 12 cases, $355; U. S. Colombia, 4 cases, $200; Venezuela, 15 packages, $259; Vienna, 9 packages, $154; Wallsend, 30 packages, $6,392.

CANADIAN NOTES.

(From our Ottawa Correspondent.)

The commissioners of Queen Victoria Park, Niagara Falls, Ont., have granted permission to the town of Niagara Falls to develop 100 horse power for town purposes and work will accordingly be commenced at once.

A party of Toronto capitalists recently consulted with Mr. William B. Rankine of Niagara Falls, N. Y., regarding the transmission of electrical power to the city of Toronto. While the details have not yet been made public it is known that arrangements are being made to transmit the power from the American side to Toronto at an early date. The development of power on the Canadian side was also discussed.

Mr. W. J. Hill of Toronto has been for the past eight months engaged in the construction of the works for the reduction plant of the Pittsburg Reduction Company at Shawinigan Falls, Que. Mr. Hill says that the company intends to go into the manufacture of aluminum. This is the first establishment of the kind in Canada, and the Pittsburg company came to this side because of the Canadian corundum deposits. The reduction works, which were built at a cost of $250,000, will be operated by electricity generated at Shawinigan Falls, which are three miles north of the city of Three Rivers, Que.

The negotiations for the purchase of the Metropolitan Electric Railway by the Toronto Railway Company are not yet concluded, and the consummation of the scheme depends upon the action of the city of Toronto. The purchasing company desires that the municipality shall guarantee a perpetual entrance to the city for cars of the various radial lines.

LEGAL NOTE.

A decree for the complainant has been granted in the United States Circuit Court of Boston, in the case of the General Electric Company vs. the Webster & Dudley Street Railway Company to enjoin the defendant from infringing letters patent number 377,996. Claims 1, 2 and 4 are in question.

INCORPORATIONS.

The Arecibo Electric Light & Water Company, East Orange, N. J. Capital stock, $300,000. Incorporators: E. J. McNulty, C. H. Tuttle and P. J. O'Leary.

The Fall Mountain Electric Light & Power Company, Bellows Falls, Vt.—to generate and supply electricity for heat, light and power. Capital stock, $100,000. Incorporators: A. N. Burbank of Brookline, Mass.; W. A. Russell of Lawrence, Mass.; L. M. Reed, J. H. Williams, P. H. Hadley, Z. H. Albee, E. S. Leonard and C. E. Howard, all of Bellows Falls.

The United States Electric Contracting Company, Syracuse, N. Y. Capital stock, $40,000. Directors: David Cronin, F. S. Rogers and E. R. Caldwell, all of Syracuse.

The Domestic Gas Light & Coke Company, New York City —to manufacture gas and electricity for light, heat and power. Capital stock, $100,000. Incorporators: J. Jackson, H. M. Thompson, both of New York City, and G. W. Linch of Montclair, N. J.

The Capitol County Light, Heat & Power Company, Watervliet, N. Y.—to manufacture gas and electricity. Capital stock, $25,000. Incorporators: D. S. Johnston, J. E. MacLean, both of Cohoes; R. Williams, of Watervleit; E. T. Chapman, Jr., of Colonie, and W. R. Condon, of Albany.

The Electro-Pneumatie Company, Hartford, Conn.—to build a pneumatic tube service between Boston and New York, by which a package can be sent between the two cities in twenty-seven minutes. Capital stock, $1,000,000. Incorporators: Charles P. Phillips, Warren K. Dowe, James L. Wolcott, Charles B. Johnson, William C. Case and Percy S. Bryant, all of New York except the two last named.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 25, 1900.

ELECTRIC RAILWAYS AND APPLIANCES.

664,459. Overhead Electric Trolley. James H. Brown and William H. Tobin, Jr., Pittsfield, Mass Filed July 10, 1900.

664,470. Construction for Third-Rail Electric Railways. William Courtenay, New York City. Filed Sept. 29, 1900.

664,579. Switch for Railways. Fred S. Pearson, Boston, Mass. Filed March 14, 1899.

664,819. Electric Safety Appliance for Railroads. Edward L. Orcutt, Somerville, Mass., assignor to the International Railroad Safety Appliance Company, Kittery, Me. Filed Jan. 3, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

664,554. Regulating Socket for Multifilament Incandescent Electric Lamps. Charles A. Hussey, New York City, assignor to William P. Pinckard, Birmingham, Ala. Filed Aug. 29, 1900.

664,713. Electric-Arc Lamp. Royal E. Ball, New York City, assignor to the Ball Electric Company, Yonkers, N. Y. Filed Sept. 21, 1899.

ELECTRICAL MACHINERY AND APPARATUS.

664,396. Dynamo-Electric Machine. Israel Fisher, Boston, Mass., assignor to Reuel W. Waters, Newton, Mass. Filed April 3, 1899.

664,649. Brush-Holder for Dynamo-Electric Machines. Christian W. Kragh, Madison, Wis., assignor to the Northern Electrical Manufacturing Company, same place. Filed Sept. 11, 1899.

664,650. Electromagnetic Ore-Separator. Emil Kreuser, Mechernich, Germany. Filed Sept. 2, 1898.

664,733. Method of Converting the Energy of Alternating Electric Currents into Effective Mechanical Energy. Rudolph Eickemeyer, Yonkers, N. Y.; Rudolf Eickemeyer, Jr., Carl Eickemeyer and Mary T. Eickemeyer executors of said Rudolf Eickemeyer, deceased. Filed Nov. 21, 1892.

TELEPHONES AND TELEPHONE APPARATUS.

664,681. Electric Call-Box. Edgar E. Salisbury, Chicago, Ill., assignor to the National Autophone Company, same place. Filed July 24, 1900.

664,691. Telephone-Exchange System. Charles Timberlake, Indianapolis, Ind. Filed Oct. 23, 1899.

664,757. Telephone-Service Apparatus. Uriah S. Jackson, Ossipee, N. H. Filed June 15, 1900.

MISCELLANEOUS.

664,369. Telegraphy. William E. Athearn, New York City. Filed April 5, 1900.

664,371. Electric Heater and Circuit-Controller Therefor. James I. Ayer, Malden, Mass., assignor to the Simplex Electrical Company, Boston, Mass. Filed May 20, 1899.

664,430. Telautograph or Facsimile Telegraph. Anton Pollak, Buda-Pesth, Austria-Hungary. Original application filed Feb. 17, 1899. Divided and this application filed Dec. 21, 1899.

664,432. Insulator. Edward Renault, Waldo, Fla. Filed May 8, 1900.

664,442 Coil for Electromagnets. Severn D. Sprong, Long Branch, N. J., assignor of two-thirds to Charles Getter and William P. Adams, same place. Filed Nov. 29, 1899.

664,503. Collector-Ring. Henry G. Reist, Schenectady, N.Y., assignor to the General Electric Company of New York. Filed March 29, 1900.

664,511. Electric Cut-Out. John H. Trumbull and Henry Trumbull, Hartford, Conn., assignors to the Trumbull Electric Company, same place. Filed April 17, 1899.

664,537. Process of Extracting Copper. James Douglas, New York City. Filed Sept. 22, 1900.

664,550. Electrolytic Treatment of Iron for Preservation Thereof. Henry L. Hollis, Chicago, Ill. Filed Feb. 20, 1899. Renewed May 16, 1900.

664,557. Telegraph-Switchboard. Francis W. Jones, New York City, assignor to the Postal Telegraph-Cable Company, same place. Filed July 16, 1900.

664,594. Means for Transmitting Motion to Distant Points. David P. Thomson, Lynn, Mass., assignor to the General Electric Company of New York. Filed Sept. 29, 1900.

664,667. Electric Push Button. Thomas A. Nathan, New York City. Filed June 1, 1900.

664,679. Accumulator. Louis Renaud, Paris, France. Filed May 24, 1900.

664,761. Printing-Telegraph. Edgar Kinsman, Malaga, N. J., assignor of one half to Alfred B. Richman, same place. Filed Dec. 21, 1899.

664,802. Fire Alarm Telegraph. Leonidas G. Woolley, Kenton, O. assignor to the National Magneto Electric Telegraph Company, Springfield, O. Filed July 20, 1900.

664,807. Electric Advertising Device. Paul Dawson, Detroit, Mich. Filed May 24, 1899.

DESIGN.

33,780. Supporting-Bracket for Telephone Receivers. Edgar C. Peixotto, Augusta, Ga. Filed Nov. 23, 1900. Term of patent 7 years.

Digitized by Google

THE TELEPHONE WORLD.

Bell Company Restrained.

A dispatch from Port Huron, Mich., says that Judge Thomas granted an injunction, restraining the Michigan Bell Telephone Company from tearing down its poles and the system of the old Harrison Telephone Company. The injunction was secured by James H. Talbot, a stockholder. It appears that after the Harrison Company was absorbed by the New State Telephone Company, after the latter had secured 175 shares of the total 300 shares of stock, thus securing a controlling interest, the New State Company, in turn, sold out to the Erie system. In some manner the Michigan Telephone Company got control of the 175 shares, and since then, it is alleged, the company has gone on with the work of destroying the old Harrison line without the consent of the other stockholders.

The injunction was asked for with a view to a second suit, which will be commenced, making the New State system, Erie Company and the Michigan Bell Company defendants.

Collector Eugene Knox, of Union Hill, N. J., sold all the poles and wires of the Postal Telegraph Company in that town December 28, at a constable's sale for unpaid taxes. The purchaser was Charles Singer, who bid one dollar, and who now demands that the town turn over to him the property which he purchased. The sale was by virtue of a warrant issued January 17, 1900, by Justice Ruh for unpaid taxes. The companies which are in arrears are the Western Union Telegraph Company, three years, $244.01; Postal Telegraph Company, two years, $151.20, and the Hudson Telephone Company, three years, $82.12. Sale of the poles and wires of the Western Union Company was prevented by an order of the Supreme Court, signed by Justice Collins. The Western Union disputes the assessment levied on its property in Union Hill on the ground that it is excessive. The assessment was $1,500 three years ago and $3,000 each year since. The company holds that it should have been $334.94 and $348.80, respectively. The question of whether the poles and wires are real or personal property is brought up, the assessors holding them as personal. This is a question new to the New Jersey courts. The Hudson Telephone Company last week obtained a reduction of its assessment and paid up, but the Postal refused to make any move except to threaten to put the collector in jail if he should interfere with its property.

The Western Electric Telephone Company of Britt, Ia. recently purchased from the Iowa & Nebraska Telephone Company the entire property of the latter company, the same consisting of 300 miles of telephone line in Northwestern Iowa and Southwestern Minnesota, and also the local telephone exchanges at the following towns: Estherville Sibley, Spirit Lake, Sheldon and Cherokee. The outside limits of the Iowa and Nebraska lines are Estherville, Rock Rapids, Rock Valley, Sheldon, Primghar, Helena, Remsen, Cherokee, Storm Lake, Laurens, Greenville and intermediate points in Iowa, with Bigelow and Ellsworth, in Minnesota. The lines described are a complete wiring of eleven counties in Northwestern Iowa, in addition to the lines that enter Minnesota.

The incorporators of the Franklin County Telephone Company met recently at St. Albans, Vt., and organized under the charter granted at the last session of the State Legislature. By-laws were adopted and the following officers elected: J. H. Abbott, president; Silas W. Flinn, vice-president; M. P. Abbott, secretary and treasurer; V. P. Abbott, auditor; directors: J. H. Abbott, George M. Gleason and M. P. Abbott. The capital stock of the company was fixed at $20,000, which was fully paid in. The business of the company has been most satisfactory for the time it has been in operation in St. Albans. There are now 317 subscribers to the system.

From reliable authority comes the news of the sale of the independent telephone line operated for the last two years by A. J. Robinson of Sanford, Me., in the towns of Sanford, Alfred, Waterboro and Kennebunk of that State. It is understood that the New England will take possession early in the year. The price is not disclosed, but is understood to have been a sum advantageous to Mr. Robinson. The recent ice storms which seriously crippled the independent line with its small repair resources is said to have precipitated the closing of the sale, for some time held in abeyance.

It has been stated on good authority, that the Jacksonville, Fla., Telephone Company and the Bell Telephone Company will soon take down their wires and place them underground. Both concerns are also expecting to erect new exchange buildings and extend their service into the State.

Work has begun on construction of the Corvallis Kings Ore., Valley telephone line.

Duplex Telephony Introduced in Chicago

A practical system of duplex telephoning, by which, using an auxiliary telephone, conversations with two persons may be held simultaneously on the same wire, has been adopted by the Chicago Telephone Company, and instruments for its operation will be put in immediately at many of the big wholesale stores and in offices where the use of the telephone is heavy. The auxiliary telephones will as a rule be used for incoming messages, but they are so arranged that out calls may be made at the same time that the main telephone is in use.

Superintendent Hibbard recently said that the plan had been thoroughly tested and proved a success. By i s use a heavy saving in the running of wires will be made besides more than doubling the capacity of the telephone service to firms using it heavily.

Two telephone companies began with the new year, operating in Pittsburg, Allegheny, Pa., and suburban towns The Central District Printing & Telegraph Company is the Bell connection. It has about 12 000 subscribers in the two cities, while the Pittsburg & Allegheny Telephone Company, a new corporation, has about 6,000. The latter started operations January 1. About 2,000 instruments have been installed in the lower part of Pittsburg, and these have been operated free about one month. The Bell representative asks for an unlimited metallic circuit for business purposes, $125 per year, while the Pittsburg & Allegheny is charging but $48 per year, and for residences $32 per year. The Bell people have a system for residences for which they charge $27 per year. These are party lines, with from two to five subscribers on one line. The new concern charges $32 straight for a single instrument on one wire. The Bell Company also has limited call instruments for which subscribers pay $27 per year for 600 calls and 5 cents per message for all over that number. It has been a difficult battle to get the independent company installed in Pittsburg. Baltimore parties have put up the money for the enterprise from the start. One concern after another failed and the franchises were repeatedly sold.

One hundred and fifty street property owners are at war in Racine, Wis., with the Citizens Telephone Company, a corporation recently organized by local capitalists, who are now putting in the system. The bone of contention is that of placing poles in front of the property. The people have filled up the pole holes as fast as workmen have dug them, and five citizens have secured injunctions restraining the company from putting in poles. Five or six others have placed dynamite cartridges under the ground, and at these places the following signs are up: "Beware! Dynamite cartridges are buried here about 2 feet from the surface. Dig at your peril."

An independent telephone line will shortly connect Memphis, Tenn., with Marion, Ark., the capital of Crittenden County. The promoters of the new enterprise are Charles Barton and Capt. J. A. Gouch. Arrrangements have been perfected for the construction of the line, and work will begin immediately. The river will be crossed by means of a cable, which will be sunk at a point a short distance above the ferry landing. It is the intention of Messrs. Barton and Gouch to continue the line to other important Arkansas towns at a later date.

The Bastin Telephone Company, recently incorporated with a capital stock of $25,000, has purchased the Crab Orchard, Stamford and Mt. Vernon, Ky., lines, the Lancaster exchange and Garrard County lines, including three exchanges and 200 miles of toll lines. The company is already at work putting up lines into new territory and improving its system. It has headquarters at Lancaster and the lines reach into Pulaski, Lincoln, Boyle, Rockcastle, Madison, Garrard, Laurel and other counties.

The Havana Telephone Company, which recently obtained a franchise in Havana and decided to install the Automatic system, is arranging for an exchange of 15,000 'phones and has obtained franchises in Cienfuegos and a half dozen other Cuban ports, some of them previously held by Lewis A. Goudy, of Portland, Me.

The Bell Telephone Company has had for years a monopoly of the business in Ames Ia. The citizens have pleaded for better service, but the Bell turned a deaf ear. Now the citizens have started an exchange of their own, and the Bell Company has awakened only to find it too late.

The citizens of Bethpage, Tenn., have organized and subscribed a telephone subsidy to build from Bethpage to Veto, Ala. The projected line will greatly add to the convenience of the two places, and will be erected at an early date.

From Mountain City, Tenn., news is received stating that the Virginia Iron, Coal & Coke Company is erecting a telephone line from its ore washer at Maymead to ore mines in Doe Mountain. The distance is four miles and the company at first decided to lessen the distance by stringing the wire across the mountain on trees, but fearing that the line would be difficult to keep up on account of falling timber, decided to let the line follow the narrow-gauge ore road.

The Tidewater Telephone Company of Tappahannock, Va., made connection and put in two long-distance telephones a short time ago. As soon as the weather permits the old wires will be pulled down and the new line completed. The line to Walkerton will be repaired. There is talk of extension from Tappahannock in various directions, and it is hoped that ere long direct connection with Richmond will be established.

The board of public works of Kansas City, Mo., lately ordered the new subway company to put its conduits 5 feet below the surface on streets, and 3 feet below the surface in alleys, it having been shown that the company had been placing conduits only 20 inches below the surface. About 1,500 feet of conduits have been laid and the work will have to be reconstructed.

Among the reforms which will be pressed in Denver, Col., when the finance committee take up the consideration of the mayor's budget will be Supervisor Mitchell's scheme for that city to build conduits and force the telephone and telegraph companies to rent space in them.

S. Cottingham has purchased the Central Union telephone plant at Deshler, O., and took possession on New Year's day. He announces that 'phone rental will be 75 cents for residences and $1.50 for offices and business rooms. This will be a great saving over the old rate.

The recently installed service of the Automatic Telephone Company is giving entire satisfaction in New Bedford, Mass. The city is furnished with free telephones and the police department has been cut off from the old system.

A franchise has been granted the Hampden Automatic Telephone Company on condition that the company furnish Westfield, Mass., free service and put such wires as the officials may stipulate under ground.

The Cumberland Telephone & Telegraph Company recently made application to the city council of Versailles, Ky., for a telephone franchise. The action was postponed until January 2.

The city council of Detroit, Mich., granted a telephone franchise to J. W. Martin last week. Mr. Martin claims he will have an exchange in operation with 3,500 subscribers within a year.

The telephone line to Danville, Ala., has been leased by the local company at Hartselle, Ala., and it is now operating the same. A line to Neel has been connected with the Danville line.

The Salem, Ill., Telephone Company has commenced the work of extending its line from Salem to Vernon, via Kinmundy of that State.

L. B. Fulgham is constructing a telephone line from Colmesneil, Tex., to the Lazarus settlement, about twelve miles east of the first town mentioned.

The Carlinville Telephone Company, located at Carlinville, Ill., certifies to an increase of capital stock from $5,000 to $30,000.

The Cane Belt telephone line is now completed five miles below Wharton, Tex., and will reach Bay City as soon as the work can be pushed ahead.

A telephone exchange will soon be established at Nashville, Ind.

TELEPHONE INCORPORATIONS.

The Subscribers' Telegraph & Telephone Company, Watervliet, N. Y. Capital stock, $15,000. Directors: D. S. Johnston and J. E. MacLean, Cohoes, and S. J. Cavanaugh of Watervliet.

The United Telephone & Telegraph Company, Wilmington, Del.—to construct and operate telephone and telegraph lines. Capital stock, $2,000,000. Incorporators: W. D. Barnard, E. Davis, E. M. Yarnall, all of Philadelphia; W. R. Bliss, of Chester, and C. M. Clements, of Sunbury, Pa.

GENERAL ELECTRICAL NEWS.

Lighting.

Annapolis, N. S.—A poll was held here recently on the electric light question when the rate-payers decided in favor of the purchase of the plant of the Odell Electric Light Company, Limited, for the sum of $8,000.

Au Sable Forks, N. Y.—The J. & J. Rogers Company of this place has put in an electric plant to add to the power of its sulphite mill on the Au Sable River, which is expected to develop 600 horse power, and to furnish sufficient to light the village with electricity.

Berlin, Conn.—The Consolidated Road's electric power plant at this place is to be enlarged to provide for a large increase in electric lighting.

Bethany, Ill.—The village board is discussing the question of erecting an electric light plant.

Bloomington, Ind.—Samuel V. Perrott of Indianapolis has secured an option on the Bloomington electric light plant, and will put in a hot-water heating system here.

Brazil, Ind. One of the improvements to be made this year is the erection of an electric lighting plant with all the latest improved and modern machinery.

Buffalo, N. Y.—The Gowanda Electric Light Company has secured the contract for lighting the streets for the next five years.

Gainesville, Ga.—A. S. Hardy proposes the organization of a company for the establishment of a light and power plant.

Indianapolis, Ind.—A. L. Phillips of this city has made a proposition to establish an electric light plant in Saybrook, Ill.

Kendrick, Idaho.—An electric light plant will be installed in the new flour mill here.

Loveland, Col.—The citizens of this place are agitating the question of erecting an electric light plant.

McKeesport, Pa.—Business men of this city are considering the advisability of organizing a new electric light company. Arrangements are on foot for the establishment of a plant and an option has been taken on a site at Fifth avenue.

McMechen, W. Va.—M. Knapp, C. P. Kinney and J. E. Doyle are interested in the organization of a company to establish a light, heat and power plant.

Memphis, Tenn.—The Memphis Electric Light & Power Company will issue $2,000,000 of bonds for improvements, including its system of conduits which will cost $500,000.. Gen. S. T. Carnes, president.

Minier Ill.—The electric light plant is to be remodeled and enlarged and a new dynamo will be installed.

Nampa, Idaho.—A franchise has been granted here for an electric light plant.

Newark, N. Y.—The village president favors the move now being agitated here for installing an electric municipal lighting plant.

New Haven, Conn.—It is understood here that a combination of New York, Bridgeport and New Haven capitalists has been organized for the purpose of applying to the Legislature this month for the incorporation of an electric light company to furnish light for this city, Milford and Bridgeport.

New Freedom, Pa.—The light committee of this place will receive bids for electric lights to light the town. W. C. Bailey and P. O. Klinefelter, commissioners.

New Sharon, Ia.—The electric light plant here is to be improved and a heating system installed.

Peebles, O.—This village is contemplating the erection of an electric light plant.

Tacoma, Wash.—This city may build an electric light plant. The council committee is investigating the cost of a first-class plant for providing power and light.

Troy, Mo.—This town is agitating the electric light question.

Valley Stream, N. Y.—It is reported here that the electric plant of the Suburban Electric Light Company has been sold to a syndicate of capitalists who propose to put the plant in operation.

Wabash, Ind.—The water system and the electric lighting system was consolidated January 1, both properties being owned by the First National Bank of New York City, which purchased the lighting plant last fall.

Waterloo, Ia.—The lighting plant here has been sold to a new company, which will expend about $50,000 on improvements.

West Plains, Mo.—A new electric light plant will soon be built at this place.

Woodbury, Pa.—The movement by the city council toward the establishment of an electric light plant is meeting with favor among the residents.

Street Railways.

Anoka, Minn.—The St. Francis Electric Railway Company has been organized to build a street railway from St. Francis to the line of Eastern Minnesota known as the cut off. The incorporators are C. Y. and J. S. Woodbury of this place, G. D. Woodbury and others.

Berlin, Wis.—The Wisconsin Midland Electric Railway Company has been incorporated to build a line between here and New London. Capitalists of Appleton are interested.

Danbury, Conn.—The Danbury & Bethel Electric Road will apply to the Legislature for permission to extend its line to the New York State border to connect there with a projected line from the Hudson River by the Peekskill Traction Company.

Defiance, O.—J. J. Frost, who is at work here getting a right of way through the town for the new Toledo-Defiance Electric Railroad, has practically completed his work.

Fordham, N. Y.—By January 15 it is expected that the Mount Vernon and New Rochelle trolley lines will run direct to the terminus of the Third Avenue Elevated at Fordham, and that the fare from New Rochelle to the City Hall will be eight cents.

Hartford, Conn.—Many new trolley lines are projected for this State.

Mankato, Minn.—Minneapolis capitalists are figuring on building an electric street railway here. A local company has a franchise to sell and the deal is likely to be consummated shortly.

Mansfield, O.—The Mansfield, Mount Gilead & Columbus Street Railway Company was incorporated a short time ago for $20,000 to build an electric street railway between the cities named in its title.

New Castle, Ind.—A. D. Ogburn and others have secured a fifty-year franchise for an electric line at this place.

Oskaloosa, Ia.—A franchise has been granted to the Oskaloosa Street Railway & Land Company giving it the right to use the streets for a street railway, a contract to furnish light to the city and the right to operate a heating plant. The company will invest $250,000 within two years.

Paris, Ill.—A. J. Hunter & Co., capitalists of Edgar County, are considering the project of constructing an electric line from this place to Clinton, Ind. The proposed line will be 20 miles in length and will cost about $160,000.

Richmond, Va.—The plans for building an electric line between this city and Petersburg are nearing completion. J. C. Robertson is the local representative of the Chicago men back of the scheme.

Romeo, Mich.—An electric railroad company is being organized here to build a road from Mt. Clemens to this place and Armada. The road is to go through Macomb and Davis to Sellick's Corner and from there to Romeo and Armada. H. N. Taylor is at the head of the project.

Scarboro, Me.—The desire for electric railroad connection with Portland and Saco is again stirring up the citizens of this place, and several petitions setting forth the need of such accommodation are being circulated and signed.

Shelbyville, Ind.—The Indianapolis, Morristown & Rushville Electric Traction Company recently received a franchise from this city for 30 years.

South Hartford, N. Y.—It is said to be a fact that a trolley line will be built from Sandy Hill through this place to Granville in the spring.

Springfield, Mass.—Capitalists are working out a project for the construction of an electric street railway line between Palmer and this city—a distance of 15 miles. The line will connect with the new road from Monson to Palmer, it will give a direct line from Springfield to all the important towns in the eastern part of Hampden County and it will fill one of the two existing gaps in the continuous line of street railway from Boston to Springfield.

Manufacturing.

Cincinnati, O.—The Creighead Engineering Company of this city has been organized for the purpose of manufacturing electrical supplies with a capital of $25,000. T. J. Creighead, J. H. Creighead, C. O. Lyon, A. J. Marsh and S. Zrelonka are among those interested.

Hartford, Conn.—It has been stated that the Perkins Electric Switch Manufacturing Company was about to remove its business to Bridgeport and abandon the factory in this city. This is emphatically denied by the management, so far as the immediate future is concerned, but it is admitted that the business will eventually be removed to Bridgeport.

New York City.—F. W. Tolley and Benjamin Wood, of South Orange, N. J., and C. F. Kinsman, of this city, are the directors of a newly-formed concern known as the Sterling Bronze Company, which has for its purpose the manufacturing of gas and electric light fixtures, with a capital of $20,000.—The John S. Bushnell Company of this city will manufacture electrical and steam appliances on a capital stock of $25,000. A. C. Lippincott of Newark, N. J., H. Spencer, and H. R. Hartt of this city are interested in the firm.

Pittsburg, Pa.—A new manufacturing firm, known as the Langton Electric & Machine Company, has recently been established in this city. The partners are Andrew G. Langton, E. V. Langton and S. M. Cote.

Washington, D. C.—The Capital City Motor Company, having for its object the construction and repair of electric motors, was lately formed. The amount of stock is fixed at $10,000. The trustees for the first year are John A. Miller, Arthus C. Balser and John J. Bell. —The E. F. Brooks Company has been organized for the manufacture, purchase and sale of gas, plumbing and electric fixtures. The officers are Clement M. Biddle, president: Emma Noud, treasurer, and Leo. C. Brooks, secretary.

Company Matters.

Paterson, N. J.—The International Power Company is contemplating the consolidation of its three big plants now situated in Providence, R. I., and Worcester, Mass., and the construction of one factory, at the cost of about $10,000,000, where all the different departments of the industry may be carried on conjointly. If the company succeeds in purchasing the Rogers Locomotive Works, for which it is now negotiating, the new plant will be erected in this city.

Stapleton, N. Y.—At the annual meeting of the stockholders of the Staten Island Electric Railroad, the following were elected directors: Samuel Thomas, W. G. Oakman, W. E. Findley, H. M. Work, J. H. Swinarton E. M. Post, John A. Hilton, D. H. Shea and G. B. M. Harvey.

Automobiles.

Boston, Mass.—It is expected that electric busses will be used on the streets of this city this week.

Chicago, Ill.—The electro motor omnibusses, being constructed by the American Car Company of St. Louis for this city, will carry 40 passengers each, the fare will be 5 cents, and no passenger will be admitted after the seats are filled.

New Haven, Conn.—The New Haven Electric Cab Company will put on Orange street next February five new electric stages for the accommodation of the increasing business of the line in that thoroughfare.

Unlisted †Nominal.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 16¾@16⅞c.; Lake, 16⅞@17c.; casting, 16⅝@16¾c.

The Syracuse (N. Y.) Rapid Transit Company has voluntarily advanced wages 7 to 9 per cent.

The United Railways & Electric Company (Baltimore) bonds are being rapidly absorbed by investors.

The gross car earnings of the Twin City Rapid Transit Company of Minneapolis for the third week of December show an average of $839 per day.

The new 4 per cent. bonds of the Third Avenue Railroad Company have been admitted to the unlisted department of the New York Stock Exchange.

The Mexican Telephone Company has declared a quarterly dividend of 2½ per cent., payable January 15. Books close January 8 and reopen January 16.

The general tone of the market for copper is steady, and no broad movement is apparently under way to influence market values sharply one way or the other.

The Central & South America Telephone Company has declared a quarterly dividend of 1½ per cent., payable January 8. Books closed December 28 and reopen January 9.

At 12:45 o'clock Monday morning the street car strike at Scranton, Pa., which was inaugurated a week ago, was called off. The men demanded what was equivalent to an advance of three cents an hour. They were allowed two cents and a ten-hour day.

A mortgage was recorded in the county clerk's office at Plainfield, N. J., Saturday, given by the Elizabeth, Plainfield & Central Jersey Traction Company to the Fidelity Trust Company of Newark. The mortgage is for $2,500,000 and is to run for fifty years at 5 per cent.

George von L. Meyer has retired from the presidency of the New England Electric Vehicle Transportation Company, as he is about to fill his post as Ambassador to Italy. Francis R. Hart, vice-president of the Old Colony Trust Company of Boston, has been elected president of the Electric Vehicle Transportation Company.

The Philadelphia "Stockholder" says: "Everybody will be surprised if Metropolitan Street Railway interests are not represented in the board of directors of the Brooklyn Rapid Transit Company, which is to be elected January 25, for everybody believes that the Metropolitan capitalists will not care to postpone longer the formal announcement of their connection with that system."

Mr. Alexander Cochrane, president pro tem. of the American Telephone & Telegraph Company, has no hopes or intentions of becoming the permanent president of that company. The directors of the company are giving the matter of the selection of a permanent president considerable attention, and at a special meeting of the board recently the subject was discussed at considerable length but without arriving at a decision.

The total income of the street railways in the State of Pennsylvania the past year was, according to the State Bureau of Railways, about $2,000,000 in excess of the previous year. Dividends amounted to $5,427,500. The total number of passengers carried was 538,194,532; total taxes paid, $1,579,284; total capital stock, $103,176,121; funded debt, $38,975,100; current liabilities, $11,585,004; total assets, $156,368,465.

At a recent meeting of stockholders of the Massachusetts Electric Companies it was voted to issue at once $2,700,000 4½ per cent. coupon notes for the purpose of purchasing stock in the sub-companies, recently authorized by the Railroad Commissioners, and retire floating debt. The indenture also provides for an additional issue of notes to the amount of $800,000 to purchase, in the future, stock of sub-companies that may be issued for improvements under the plan of consolidating the properties.

Henry Hart, formerly president of the Third Avenue Railroad Company of New York and his friends have completed negotiations whereby they will secure funds to "call" from James R. Keene and a pool of Wall Street brokerage houses the block of Third Avenue stock taken from Mr. Hart a year ago in order to protect him from the then impending crash. One of the provisions of this arrangement was that Mr. Hart had the right to take back his stock at any time within a year.

The figures of the Manhattan Elevated Railway Company of New York, as given in the annual report to stockholders, support the contention of those connected with the company that the passengers carried for 1901 will probably reach 190,000,000, a figure that has not been touched since 1894. This increase in travel should not mean any large increase in expense, pending the installation of electricity, for in 1893 the company handled 30,000,000 more passengers than this with 1,000,000 less train mileage.

The Brooklyn "Eagle" says: "The personnel of the board of directors of the Brooklyn Rapid Transit Company to be chosen in January has been agreed upon and will show some changes. Since the annual report $1,000,000 floating debt has been paid off without increasing the funded debt with money largely received from committees engaged in the reorganization of the Kings County Elevated and Brooklyn Elevated. The company has nearly $1,000,000 cash surplus in its banks, but no dividend is expected until July."

The New York "News Bureau" states that the rumor is again rife that the People's Gas Company of Chicago has made some arrangement with the Edison Company and to this report the rise in the stock is attributed. Officials of the gas company, when asked concerning the matter, said that only the friendly feeling which is of long standing existed and that no closer alliance had been formed. President Insull, of the Chicago Edison Company, met the inquiry with his usual attitude of indifference, pleaded ignorance of the story and remained non-committal about the probabilities of such a step.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Shop foreman for an electrical repair works; repairing generator and motors, also railway motor and controller work. The applicant must be up-to-date as a machinist, and capable of handling men to advantage; steady position and good pay to one who can fill requirements Address ENERGY, care ELECTRICITY.

WANTED.—A practical engineer and electrician to superintend and run a small electric light plant in a nice country town (the county seat); must understand in and outside wiring, repairing and constructing, one who can buy an interest in the plant preferred; this is a splendid opening for the right man; references required. Address MOTOR, care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Position to take charge of electric light plant; understand inside and outside construction work; have had a college course; good mechanical draughtsman; can give best of references. Address SUMNER, care ELECTRICITY.

WANTED.—Married man, age 25, would like to take charge of a small plant in the West and run same, not afraid of work; 8 years' experience in all kinds of electrical work; have put in two plants complete; understand all engine work, pumps and boilers; can furnish good references. Address J. W. A., care ELECTRICITY.

WANTED.—By a young man, age 24, position as assistant engineer and dynamo tender in electric plant, or with sume good electrician in a town where there is lots to do; have studied the construction of dynamos and motors and have had some experience; have worked about steam engines and in a machine shop; good references. Address H. H G., care ELECTRICITY.

WANTED.—Position as salesmen for electricity supplies, etc., in Eastern Pennsylvania. Address W. G. L., care ELECTRICITY.

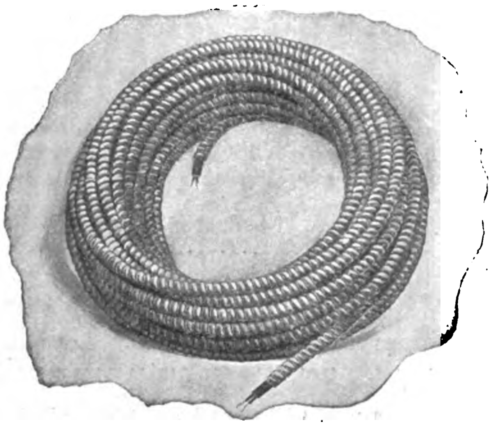
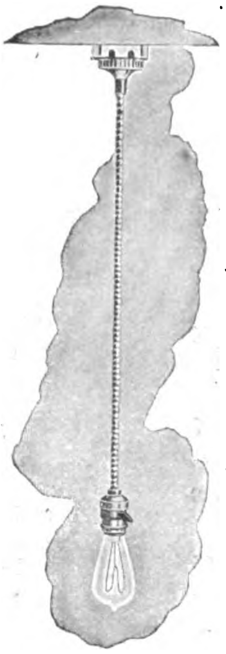
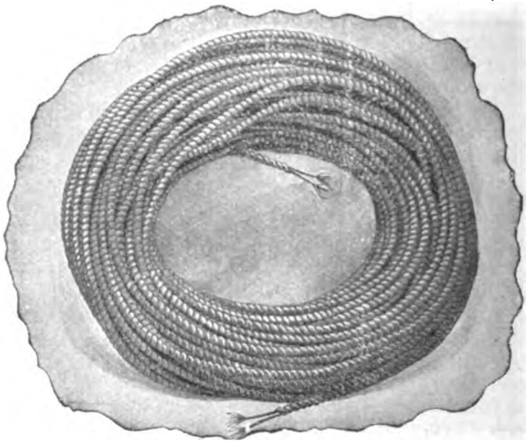
GREENFIELD

Flexible Steel Armored Conductors.







The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.

The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

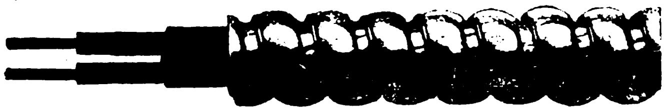
These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.



Section of Flexible Steel Armored Cable.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors—Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocyclic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99. Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

WHAT CAN WE DO FOR YOU IN WASHINGTON?
Hon. A. S. Hewitt, ex-Mayor of New York, and of the Iron Manufacturing Firm of Cooper, Hewitt & Co., says:
"If your facilities were made sufficiently known, they would be generally resorted to for information and advice. I shall not only use your office for my own satisfaction, but will recommend you to my friends who may come to me for advice. I am very much interested in the possibilities of usefulness which you open to enterprising business managers in this country. You have laid the foundation of a most useful undertaking upon a very broad basis."

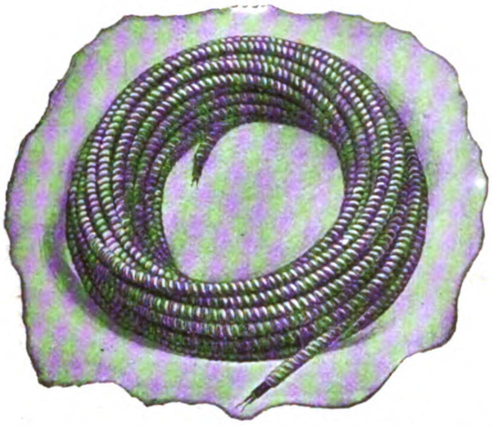
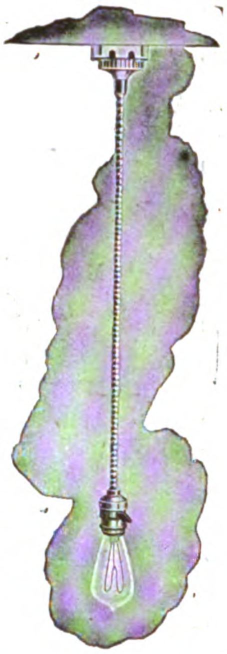
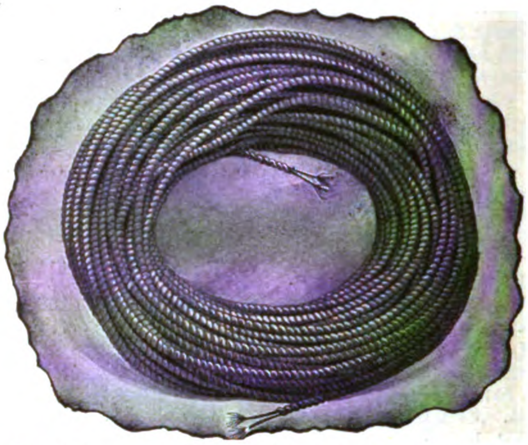
GREENFIELD

Flexible Steel Armored Conductors.







The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.

The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.

COPY. DEPARTMENT OF THE INTERIOR,
WASHINGTON.

DEAR SIR: December 2d, 1887.

I have received yours of Nov. 29, and have in reply to state that your resignation as Principal Examiner in charge of electricity in the United States Patent Office took effect on April 1, 1887. You were for three years the Electrical Expert in charge of the class of electricity in that office. From the best of my knowledge and belief you were competent to pass fully and intelligently upon all matters requiring electrical expert knowledge concerning inventions, etc. Your reputation in this respect was high, not only in the Department, but outside. I wish you success in your new business.

With kind feeling, I have the honor to remain,

Very truly yours,
L. Q. C. LAMAR,
Sec'y Interior.

Mr. CHAS. J. KINTNER,
265 Broadway,
New York City.

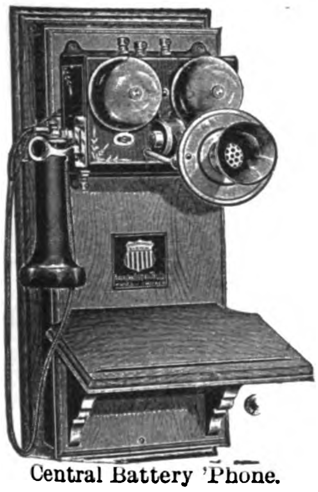
MANUFACTURERS OF

All kinds of High-Class Telephone Equipment.
Enlarged Factory. Increased Facilities.



Central Battery 'Phone.

Multiple Switchbords for Central Battery and Magneto Systems.

Toll Line Boards to Meet any Requirement.

Our 1900 Telephones
Bridged and Series, are Unexcelled.

Output 1,000 per Week.

Our New Cable Terminal with Improved Sneak-Current Protector and Carbon Arrester is a Great Success.

Distributing Boards, Repeating Coils, Lightning Arresters and Construction Supplies of All Kinds. Correspondence Solicited.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors—Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocyiic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99 Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Shop foreman for an electrical repair works; repairing generator and motors, also railway motor and controller work. The applicant must be up-to-date as a machinist, and capable of handling men to advantage; steady position and good pay to one who can fill requirements Address ENERGY, care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Position by an experienced man; has had charge of a large road, and has been connected with motor departments for several years in testing and installing street car equipments; best of references furnished. Address ELECTRIC, care ELECTRICITY.

WANTED.—Position in Illinois at firing or as oiler; have studied steam power and have fired on steamers on the Mississippi and Delaware Rivers. Address F. S., care ELECTRICITY.

WANTED.—By young man situation with electrical firm where there would be a chance to improve and learn; strictly temperate. Address J. E. M., care ELECTRICITY.

WANTED.—Position by a practical electrician and steam engineer of good business ability as superintendent of electrical light plant in small city; at present time am operating about 250 KW. 2-phase alternating successfully; change of location wished; references present concern. Address H., care ELECTRICITY.

WANTED.—Position by a thoroughly practical electrical engineer and machinist as superintendent of electric light or power plant at moderate pay; first class references; 20 years' experience; good construction man; expert storage battery man. Address EXPERT, care ELECTRICITY.

WANTED.—Position as electrician of light and power plant; have had 8 years experience in direct and alternating current work and am up to-date on two and three phase work and apparatus; modern, economical methods and good business man; salary moderate. Address BUSINESS, care ELECTRICITY.

THIS BUSINESS ADVERTISES ITSELF.

One of the unique features of the New York Central's "Lake Shore Limited" is the fact that it advertises itself.

The magnificence of the service and completeness of detail makes every patron an advertiser of its merits.

It is estimated that every person who travels by this train brings at least a dozen new patrons.

"The Lake Shore Limited" leaves Grand Central Station, New York, every afternoon at 5.30 and arrives Chicago via Lake Shore & Michigan Southern Railway the next afternoon at 4.30.

Returning, leaves Chicago 5.30 P. M. each day, arrives New York 6.30 next afternoon.

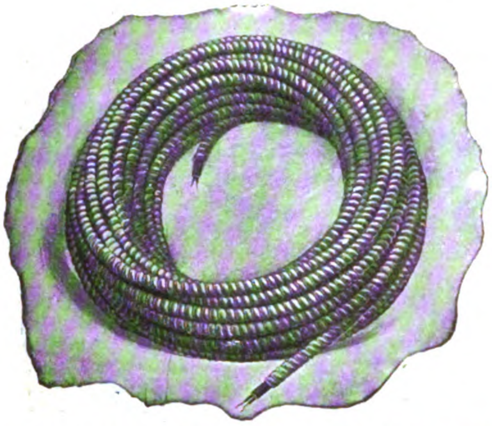
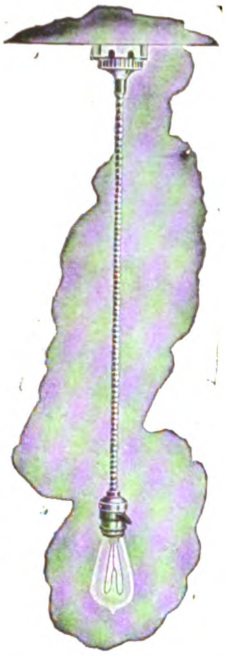
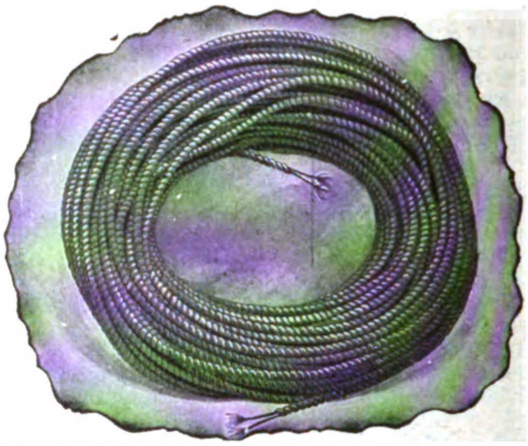
GREENFIELD

Flexible Steel Armored Conductors.



The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.





The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.

COPY. DEPARTMENT OF THE INTERIOR, WASHINGTON.

DEAR SIR: December 2d, 1887.

I have received yours of Nov. 29, and have in reply to state that your resignation as Principal Examiner in charge of electricity in the United States Patent Office took effect on April 1, 1887. You were for three years the Electrical Expert in charge of the class of electricity in that office. From the best of my knowledge and belief you were competent to pass fully and intelligently upon all matters requiring electrical expert knowledge concerning inventions, etc. Your reputation in this respect was high, not only in the Department, but outside. I wish you success in your new business.

With kind feeling, I have the honor to remain,

Very truly yours,
L. Q. C. LAMAR,
Sec'y Interior.

Mr. Chas. J. Kintner,
265 Broadway,
New York City.

Chas. J. Kintner, Esq.,
45 Broadway, N. Y.

Dear Sir:—Your favor dated 18th inst., with enclosed notice of allowance and copy of claims as allowed received. It gives me great pleasure to be able to acknowledge not only the conscientiousness of your work, but also the great ingenuity displayed in the wording of the claims. In about two or three weeks I will be able to notify you in what foreign countries patents should be applied for.

Till then I beg to remain, yours very truly,
DR. I. KITSEE.

Dynamo-Electric Machinery:

Its Construction, Design and Operation.

BY

PROF. SAMUEL SHELDON, A. M. Ph. D.,

Professor of Physics and Electrical Engineering, Polytechnic Institute of Brooklyn,

Assisted by HOBART MASON, B. S.

DIRECT CURRENT MACHINES.

PREFACE..

This book is intended to be used, primarily, in connection with instruction on courses of electrical engineering, in institutions for technical education. It is intended equally as much for the general reader, as well as a book of reference for engineers.

The first two chapters are devoted to a brief but logical discussion of the electrical and magnetic laws and facts upon which the operation of this class of machinery depends.

CONTENTS.

CHAPTER I.—Electrical Laws and Facts. II.—Magnetic Laws and Facts. III.—Armatures. IV.—Field Magnets. V.—Operation of Armatures. VI.—Efficiency of Operation. VII.—Constant Potential Dynamos. VIII.—Constant Current Dynamos. IX.—Motors. X.—Series Motors. XI.—Dynamoters, Motor-Generators and Boosters. XII.—Management of Machines. XIII.—The Design of Machines. XIV.—Tests.

D. VAN NOSTRAND COMPANY, Publishers,
23 Murray and 27 Warren Sts., New York.

*** Copies sent prepaid on receipt of price.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors - Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocylic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99 Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—An electrician familiar with alternators and dynamos, and competent and willing to do line work, house-wiring, lamp-repairing, and the work generally of a plant and its connections, for a northern New York light and power plant. Address ST. LAWRENCE, care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Position as superintendent or inspector of a telephone exchange by a man of 12 years' experience in electrical work, and who thoroughly understands switchboards, instruments and construction work. Address COMPETENT, care ELECTRICITY.

WANTED.—Position as superintendent in a large plant by a mechanical and electrical engineer; familiar with all classes of work; good references. Address S. R. B., care ELECTRICITY.

WANTED.—Position by a young man, 25 years of age, graduate of electrical course in leading technical college; has had practical experience in electrical and mechanical work; best references; location in Eastern States preferred. Address WORKER, care ELECTRICITY.

WANTED.—Position; clean record; 4 years' foreman building street cars; 8 years building and superintendent electric street railroad; 2 years' installing electric light plants; a hustler. Address W. R. M., care ELECTRICITY.

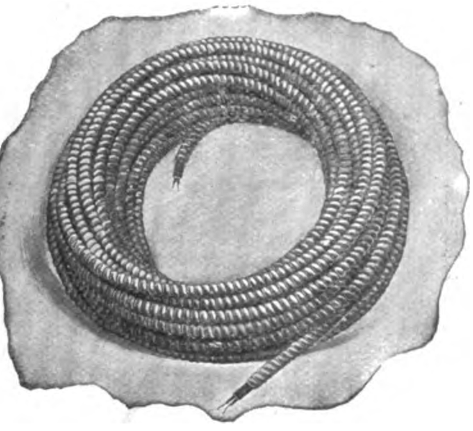
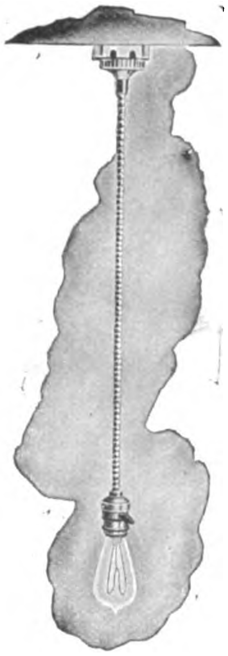
ELECTRICITY NEWSPAPER CO., 136 Liberty St., New York.

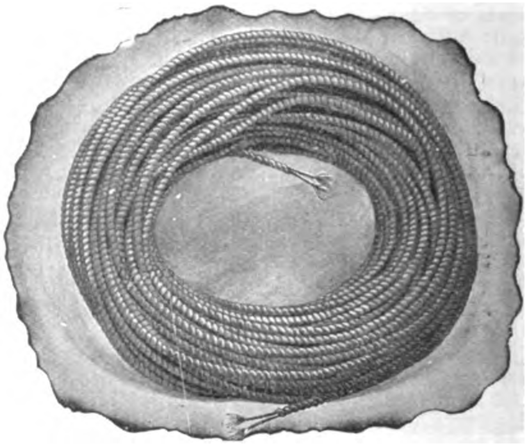
GREENFIELD

Flexible Steel Armored Conductors.



The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.





The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

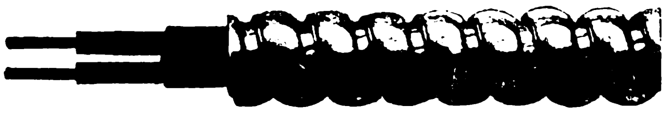
These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.



Section of Flexible Steel Armored Cable.

THE NEW SHELBY LAMP!!

50 to 100 per cent more useful light.

Send for our pamphlet containing opinions and report of tests made by people you know.

Lamps almost invariably hang downward above the horizontal line of vision.

Objects to be illuminated are beneath.

Light travels in straight lines.

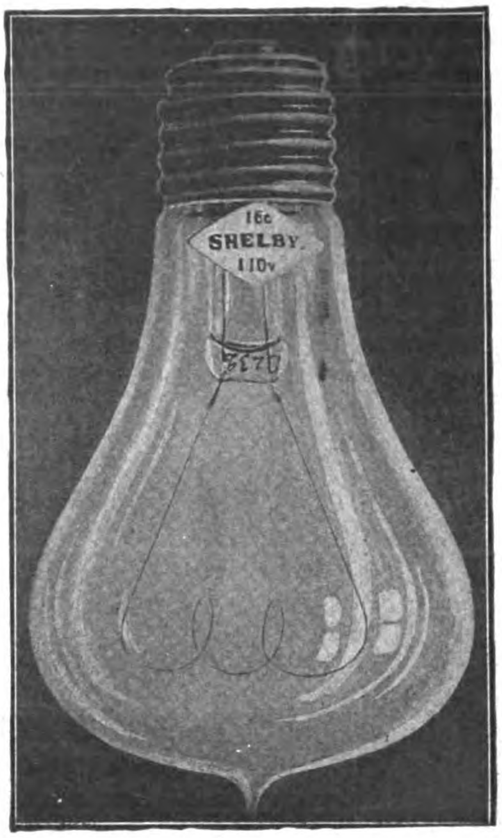
Therefore

THE USEFUL LIGHT is that passing through the end of the lamp.

Think it over.

You want the most light for current consumed.

Patent applied for.



Shelby 10 candle-power lamps consume 40 per cent less current than any make, 16 candle-power.

Shelby 10 candle-power lamps give more USEFUL LIGHT than any single, anchored or double filament lamp of 16 candle-power.

Why do you consider efficiency of light wasted?

There is every reason why you should consider efficiency or cost of light utilized.

Observe candle-power and efficiency in table below. Which is the most economical lamp or which gives the most light of value, for current consumed?

If reflectors are used, or if you consider reflected light from any source, Shelby lamps give an equal amount to reflect.

COPY. DEPARTMENT OF THE INTERIOR, WASHINGTON.

DEAR SIR: December 2d, 1887.

I have received yours of Nov. 29, and have in reply to state that your resignation as Principal Examiner in charge of electricity in the United States Patent Office took effect on April 1, 1887. You were for three years the Electrical Expert in charge of the class of electricity in that office. From the best of my knowledge and belief you were competent to pass fully and intelligently upon all matters requiring electrical expert knowledge concerning inventions, etc. Your reputation in this respect was high, not only in the Department, but outside. I wish you success in your new business.

With kind feeling, I have the honor to remain,

Very truly yours,
L. Q. C. LAMAR,
Sec'y Interior.

Mr. CHAS. J. KINTNER,
265 Broadway,
New York City.

ELECTRICAL PATENTS

DR. I. KITSEE,
ANALYTICAL CHEMIST,
(Graduate Vienna)
ELECTRICAL EXPERT,
NO. 306 STOCK EXCHANGE PLACE.

Philadelphia, May 20, 1896.

CHAS. J. KINTNER, Esq.,
45 Broadway, N. Y.

Dear Sir:—Your favor dated 18th inst., with enclosed notice of allowance and copy of claims as allowed received. It gives me great pleasure to be able to acknowledge not only the conscientiousness of your work, but also the great ingenuity displayed in the wording of the claims. In about two or three weeks I will be able to notify you in what foreign countries patents should be applied for.

Till then I beg to remain, yours very truly,
DR. I. KITSEE.

CHAS. J. KINTNER, Solicitor of Domestic and Foreign Patents, 45 Broadway, New York.
Late Principal Examiner U. S. Patent Office

STANDARD WIRING
For Electric Light and Power.

By H. C. CUSHING, JR., A. I. E. E.,
Electrical Engineer and Inspector.

The Universally Adopted National Electrical Code explained and illustrated in this handbook.

ADOPTED by the Fire Underwriters of the United States, by Cornell University, Stanford University and other technical colleges and schools, by over 27,000 Electrical Engineers, Central Station Managers and Wiremen—

BECAUSE it is the only book on Wiring and Construction kept strictly up-to-date. It contains all the necessary Tables, Rules, Formulæ and illustrations. It settles disputes, and if referred to before wiring will prevent disputes.

Dynamo-Electric Machinery:

Its Construction, Design and Operation.

BY

PROF. SAMUEL SHELDON, A. M. Ph. D.,

Professor of Physics and Electrical Engineering, Polytechnic Institute of Brooklyn,

Assisted by HOBART MASON, B. S.

DIRECT CURRENT MACHINES.

PREFACE.

This book is intended to be used, primarily, in connection with instruction on courses of electrical engineering, in institutions for technical education. It is intended equally as much for the general reader, as well as a book of reference for engineers.

The first two chapters are devoted to a brief but logical discussion of the electrical and magnetic laws and facts upon which the operation of this class of machinery depends.

CONTENTS.

CHAPTER I.—Electrical Laws and Facts. II.—Magnetic Laws and Facts. III.—Armatures. IV.—Field Magnets. V.—Operation of Armatures. VI.—Efficiency of Operation. VII.—Constant Potential Dynamos. VIII.—Constant Current Dynamos. IX.—Motors. X.—Series Motors. XI.—Dynamoters, Motor-Generators and Boosters. XII.—Management of Machines. XIII.—The Design of Machines. XIV.—Tests.

D. VAN NOSTRAND COMPANY, Publishers,

23 Murray and 27 Warren Sts., New York.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors—Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocyclic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99. Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—An A1 practical, reliable engineer to take charge of a plant with two Corliss engines, Brush arc machines, T.-H. alternating and Westinghouse generators; a machinist preferred; Southern position. Address ENGINEER, care ELECTRICITY.

WANTED.—A good inside lineman, one capable of taking charge of estimating on wiring, and men doing such work; must understand alternating arc lamps and open arc lamps; Southern position. Address LINEMAN, care ELECTRICITY.

WANTED.—Good car mechanic; one that can wire cars and keep up the repairs on G. E. 800 and Edison No. 14 motors, and make himself generally useful in the car department. Address MECHANIC, care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Position by an experienced young married man as superintendent of an electric light plant in a city of 30,000 or less, or superintendent of an electric light construction company; understand contracting work. Address C. M. W., care ELECTRICITY.

WANTED.—Position as superintendent or chief engineer of electric light plant; six years' experience as superintendent of light plant, ice and water combined; can do all kinds of electrical work from ground up; understand construction work and interior wiring; am now employed as chief engineer but wish a change; am married man and strictly sober; best of recommendations. Address J. D. H., care ELECTRICITY.

WANTED.—Position with an electric railway company by a young man of seven years' experience in construction and maintenance work; good references furnished. Address DENNISON, care ELECTRICITY.

WANTED.—Position in engineering department of electrical manufacturing concern by technical graduate 23 years of age; highest references; good draughtsman; open to any fair opportunity in electrical line. Address R. G. P., care ELECTRICITY.

WANTED.—Position in telephone exchange as superintendent or inspector by a man with 12 years' experience in electrical work; understands telephone, switchboard and construction work; am employed by a manufacturing company. Address MANUFACTURER, care ELECTRICITY.

COPY. DEPARTMENT OF THE INTERIOR, WASHINGTON.

DEAR SIR: December 2d, 1887.

I have received yours of Nov. 29, and have in reply to state that your resignation as Principal Examiner in charge of electricity in the United States Patent Office took effect on April 1, 1887. You were for three years the Electrical Expert in charge of the class of electricity in that office. From the best of my knowledge and belief you were competent to pass fully and intelligently upon all matters requiring electrical expert knowledge concerning inventions, etc. Your reputation in this respect was high, not only in the Department, but outside. I wish you success in your new business.

With kind feeling, I have the honor to remain,

Very truly yours,
L. Q. C. LAMAR,
Sec'y Interior.

Mr. Chas. J. Kintner,

Dynamo-Electric Machinery:

Its Construction, Design and Operation.

BY

PROF. SAMUEL SHELDON, A. M. Ph. D.,

Professor of Physics and Electrical Engineering, Polytechnic Institute of Brooklyn,

Assisted by HOBART MASON, B. S.

DIRECT CURRENT MACHINES.

PREFACE.

This book is intended to be used, primarily, in connection with instruction on courses of electrical engineering, in institutions for technical education. It is intended equally as much for the general reader, as well as a book of reference for engineers.

The first two chapters are devoted to a brief but logical discussion of the electrical and magnetic laws and facts upon which the operation of this class of machinery depends.

CONTENTS.

CHAPTER I.—Electrical Laws and Facts. II.—Magnetic Laws and Facts. III.—Armatures. IV.—Field Magnets. V.—Operation of Armatures. VI.—Efficiency of Operation. VII.—Constant Potential Dynamos. VIII.—Constant Current Dynamos. IX.—Motors. X.—Series Motors. XI.—Dynamoters, Motor-Generators and Boosters. XII.—Management of Machines. XIII.—The Design of Machines. XIV.—Tests.

D. VAN NOSTRAND COMPANY, Publishers,
23 Murray and 27 Warren Sts., New York.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors - Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocyclic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99 Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

WHAT CAN WE DO FOR YOU IN WASHINGTON?
Hon. A. S. Hewitt, ex-Mayor of New York, and of the Iron Manufacturing Firm of Cooper, Hewitt & Co., says:

"If your facilities were made sufficiently known, they would be generally resorted to for information and advice. I shall not only use your office for my own satisfaction, but will recommend you to my friends who may come to me for advice. I am very much interested in the possibilities of usefulness which you open to enterprising business managers in this country. You have laid the foundation of a most useful undertaking upon a very broad basis."

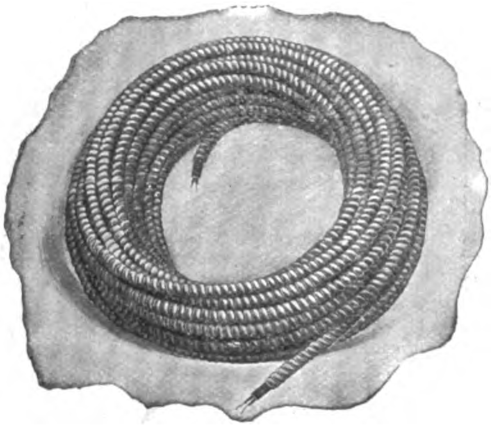
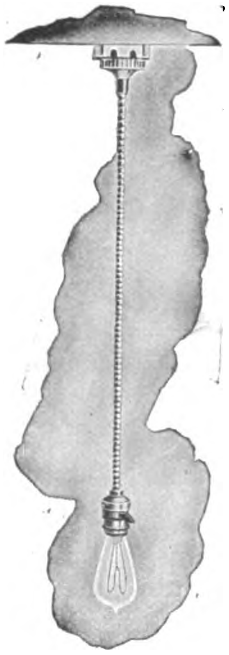
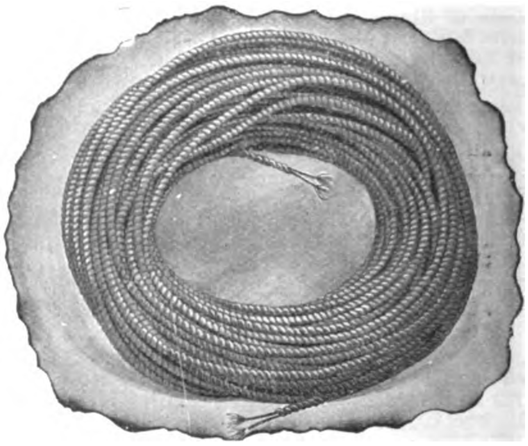
GREENFIELD

Flexible Steel Armored Conductors.







The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.

The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

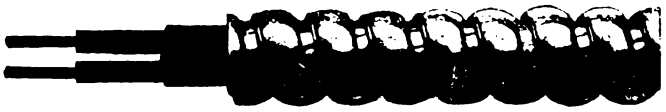
These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.



Section of Flexible Steel Armored Cable.

THE NEW SHELBY LAMP!!

50 to 100 per cent more useful light.

Send for our pamphlet containing opinions and report of tests made by people you know.

Lamps almost invariably hang downward above the horizontal line of vision.

Objects to be illuminated are beneath.

Light travels in straight lines.

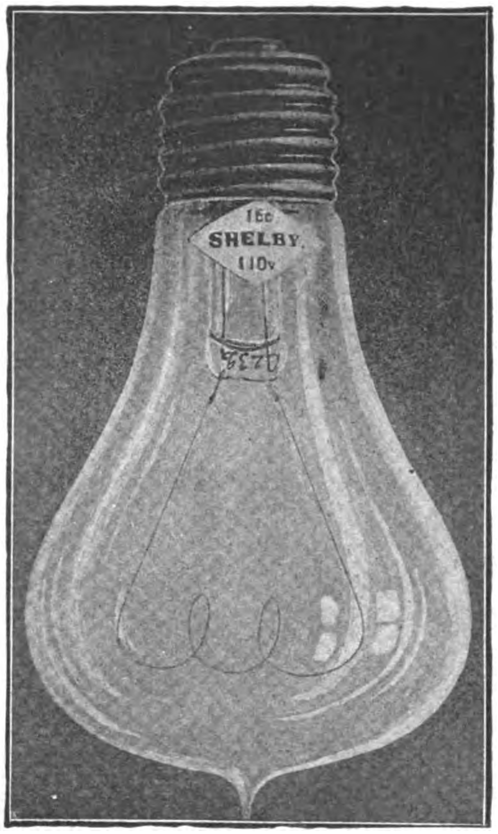
Therefore

THE USEFUL LIGHT is that passing through the end of the lamp.

Think it over.

You want the most light for current consumed.

Patent applied for.



Shelby 10 candle-power lamps consume 40 per cent. less current than any make, 16 candle-power.

Shelby 10 candle-power lamps give more USEFUL LIGHT than any single, anchored or double filament lamp of 16 candle-power.

Why do you consider efficiency of light wasted ?

There is every reason why you should consider efficiency or cost of light utilized.

Observe candle-power and efficiency in table below. Whi[illegible] is the most economical lam[illegible] which gives the most ligh[illegible] value, for current consume[illegible]

If reflectors are used, or if [illegible] consider reflected light [illegible] any source, Shelby lamps [illegible] an equal amount to reflect[illegible]

COPY. DEPARTMENT OF THE INTERIOR,
WASHINGTON.

DEAR SIR: December 2d, 1887.

I have received yours of Nov. 29, and have in reply to state that your resignation as Principal Examiner in charge of electricity in the United States Patent Office took effect on April 1, 1887. You were for three years the Electrical Expert in charge of the class of electricity in that office. From the best of my knowledge and belief you were competent to pass fully and intelligently upon all matters requiring electrical expert knowledge concerning inventions, etc. Your reputation in this respect was high, not only in the Department, but outside. I wish you success in your new business.

With kind feeling, I have the honor to remain,

Very truly yours,
L. Q. C. LAMAR,
Sec'y Interior.

Mr. CHAS. J. KINTNER,
265 Broadway,
New York City.

ELECTRICAL PATENTS

DR. I. KITSEE,

(*Graduate Vienna*)
ELECTRICAL EXPERT,
No. 306 STOCK EXCHANGE PLACE.

Philadelphia, May 20, 1896.

CHAS. J. KINTNER, Esq.,
45 Broadway, N. Y.

Dear Sir:—Your favor dated 18th inst., with enclosed notice of allowance and copy of claims as allowed received. It gives me great pleasure to be able to acknowledge not only the conscientiousness of your work, but also the great ingenuity displayed in the wording of the claims. In about two or three weeks I will be able to notify you in what foreign countries patents should be applied for.

Till then I beg to remain, yours very truly,
DR. I. KITSEE.

CHAS. J. KINTNER, Solicitor of Domestic and Foreign Patents, 45 Broadway, New York.

Dynamo-Electric Machinery:

Its Construction, Design and Operation.

BY

PROF. SAMUEL SHELDON, A. M. Ph. D.,

Professor of Physics and Electrical Engineering, Polytechnic Institute of Brooklyn,

Assisted by HOBART MASON, B. S.

DIRECT CURRENT MACHINES.

PREFACE.

This book is intended to be used, primarily, in connection with instruction on courses of electrical engineering, in institutions for technical education. It is intended equally as much for the general reader, as well as a book of reference for engineers.

The first two chapters are devoted to a brief but logical discussion of the electrical and magnetic laws and facts upon which the operation of this class of machinery depends.

CONTENTS.

CHAPTER I.—Electrical Laws and Facts. II.—Magnetic Laws and Facts. III.—Armatures. IV.—Field Magnets. V.—Operation of Armatures. VI.—Efficiency of Operation. VII.—Constant Potential Dynamos. VIII.—Constant Current Dynamos. IX.—Motors. X.—Series Motors. XI.—Dynamoters, Motor-Generators and Boosters. XII.—Management of Machines. XIII.—The Design of Machines. XIV.—Tests.

D. VAN NOSTRAND COMPANY, Publishers,
23 Murray and 27 Warren Sts., New York.

Standard Polyphase Apparatus and Systems.

..BY..

MAURICE A. OUDIN, M. S.
Member A. I. E. E.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors—Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocylic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99. Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—An A1 practical, reliable engineer to take charge of a plant with two Corliss engines, Brush arc machines, T.-H. alternating and Westinghouse generators; a machinist preferred; Southern position. Address ENGINEER, care ELECTRICITY.

WANTED.—A good inside lineman, one capable of taking charge of estimating on wiring, and men doing such work; must understand alternating arc lamps and open arc lamps; Southern position. Address LINEMAN, care ELECTRICITY.

WANTED.—Good car mechanic; one that can wire cars and keep up the repairs on G. E. 800 and Edison No. 14 motors, and make himself generally useful in the car department. Address MECHANIC, care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Position by an experienced young married man as superintendent of an electric light plant in a city of 30,000 or less, or superintendent of an electric light construction company; understand contracting work. Address C. M. W., care ELECTRICITY.

WANTED.—Position as superintendent or chief engineer of electric light plant; six years' experience as superintendent of light plant, ice and water combined; can do all kinds of electrical work from ground up; understand construction work and interior wiring; am now employed as chief engineer but wish a change; am married man and strictly sober; best of recommendations. Address J. D. H., care ELECTRICITY.

WANTED.—Position with an electric railway company by a young man of seven years' experience in construction and maintenance work; good references furnished. Address DENNISON, care ELECTRICITY.

WANTED.—Position in engineering department of electrical manufacturing concern by technical graduate 23 years of age; highest references; good draughtsman; open to any fair opportunity in electrical line. Address R. G. P., care ELECTRICITY.

WANTED.—Position in telephone exchange as superintendent or inspector by a man with 12 years' experience in electrical work: understands telephone, switchboard and construction work; am employed by a manufacturing company. Address MANUFACTURER, care ELECTRICITY.

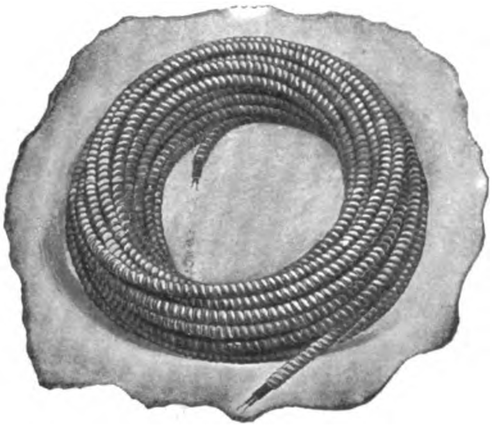
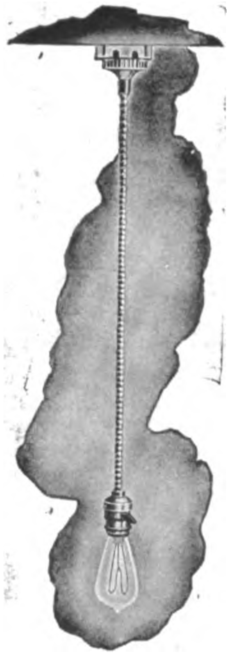
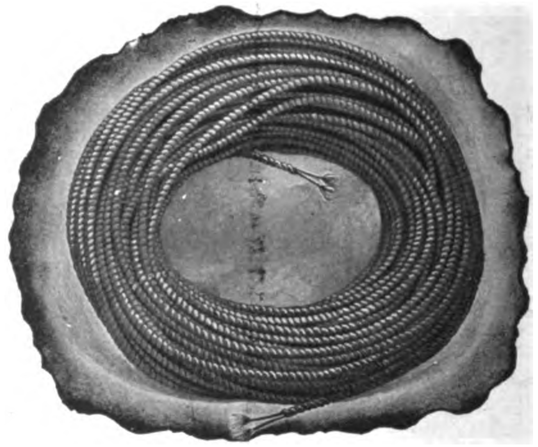
GREENFIELD

Flexible Steel Armored Conductors.







The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.

The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.

ELECTRIC LIGHT HOME

Teaches how to obtain Electric Light from Home-Made Primary Batteries.
Address
J. H. MASON, E. E.,
170 West Broadway, New York City, U. S. A.

We DON'T make big motors, but we DO make SMALL ones from 1-20 to 1 horse power, and good ones, too. If you are a user of small motors and have never tried ours you are doing yourself an injustice.

We make gas engine igniters, small air compressors, motor dynamos, etc.

Our prices are right. Send for catalogue.

Victor Electric Co.,

THE NEW SHELBY LAMP!!

50 to 100 per cent more useful light.

Send for our pamphlet containing opinions and report of tests made by people you know.

Lamps almost invariably hang downward above the horizontal line of vision.

Objects to be illuminated are beneath.

Light travels in straight lines.

Therefore

THE USEFUL LIGHT is that passing through the end of the lamp.

Think it over.

You want the most light for current consumed.

Patent applied for.

Shelby 10 candle-power lamps consume 40 per cent less current than any make, 16 candle-power.

Shelby 10 candle-power lamps give more USEFUL LIGHT than any single, anchored or double filament lamp of 16 candle-power.

Why do you consider efficiency or light wasted?

There is every reason why you should consider efficiency or cost of light utilized.

Observe candle-power and efficiency in table below. Which is the most economical lamp or which gives the most light of value, for current consumed?

If reflectors are used, or if you consider reflected light from any source, Shelby lamps give an equal amount to reflect.

	C. P. Horizontal.	C. P. Vertical. (Useful Rays.)	When Efficiency Horizontal is	Efficiency (Useful Rays.)

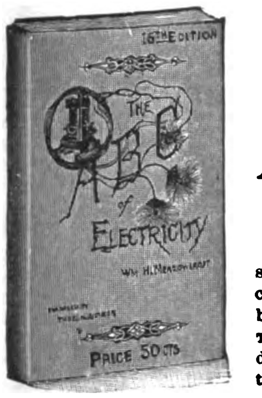
Popular Electrical Books.



A. B. C. of Electricity.

BY WILLIAM H. MEADOWCROFT,
Endorsed by Thos. A. Edison.

A Plain Book for Plain People

1 vol. 12 mo. Cloth. Illustrated.

This excellent primary BOOK has taken FIRST PLACE in elementary SCIENTIFIC WORKS, having enjoyed AN ACTUAL SALE of over 67,000 copies. The A. B. C. principles, upon which ELECTRICAL SCIENCE is built, are set forth in a CLEAR and CONCISE MANNER. The INFORMATION it contains is VALUABLE and CORRECT. It is for EVERY PERSON desiring a KNOWLEDGE OF ELECTRICITY and is what its title implies, the first flight of steps in electricity. PRICE 50 CENTS.

A. B. C. of the X-Rays.

By Wm. H. Meadowcroft.

This is the best primary work on the subject. The aim of the book is to explain the whole apparatus and the manner of its working in a popular and practical way. Fully illustrated. 12mo. Cloth. Price 75 cents.

Electrical Instrument Making for Amateurs.

By S. R. Bottone. 200 pages. Cloth. Contains plain instructions by which any one with an ordinary knowledge of English and moderately handy with tools can make the instruments now employed in theoretical or practical electricity, from Torsion balances, Holtz machines and induction coils to dynamos, electric motors, telephones, phonographs and micrographs. Price 50 cents.

Electric Bells and All About Them.

By S. R. Bottone. 196 pages, 100 illustrations. Cloth. In this volume the whole subject of electric bells is explained in simple language. Any one with an English education can master it in a few hours. Price 50 cents.

Electro Motors—How Made and How Used.

A hand-book for amateurs and practical men. By S. R. Bottone and A. M. A. Beale. 164 pages. Cloth. A complete and simple explanation of the source of the power in a dynamo and the method of applying the same. Price 75 cents.

How to Make a Dynamo.

By Alfred Crofts. Cloth, large 12mo. A practical work for amateurs and electricians, containing numerous illustrations and detailed instructions for constructing dynamos of all sizes to produce electric light. Price 75 cents.

Any of the above books sent postpaid upon receipt of price.

Dynamo-Electric Machinery:

Its Construction, Design and Operation.

BY

PROF. SAMUEL SHELDON, A. M. Ph. D.,

Professor of Physics and Electrical Engineering, Polytechnic Institute of Brooklyn,

Assisted by HOBART MASON, B. S.

DIRECT CURRENT MACHINES.

PREFACE.

This book is intended to be used, primarily, in connection with instruction on courses of electrical engineering, in institutions for technical education. It is intended equally as much for the general reader, as well as a book of reference for engineers.

The first two chapters are devoted to a brief but logical discussion of the electrical and magnetic laws and facts upon which the operation of this class of machinery depends.

CONTENTS.

CHAPTER I.—Electrical Laws and Facts. II.—Magnetic Laws and Facts. III.—Armatures. IV.—Field Magnets. V.—Operation of Armatures. VI.—Efficiency of Operation. VII.—Constant Potential Dynamos. VIII.—Constant Current Dynamos. IX.—Motors. X.—Series Motors. XI.—Dynamoters, Motor-Generators and Boosters. XII.—Management of Machines. XIII.—The Design of Machines. XIV.—Tests.

D. VAN NOSTRAND COMPANY, Publishers,

23 Murray and 27 Warren Sts., New York.

CONTENTS.

Introductory—Generators—Generators, Concluded—Induction Motors—Synchronous Motors—Rotary Converters—Static Transformers—Station Equipment and General Apparatus—Two phase System—Three-phase System—Monocylic System—Frequency—Relative Weights of Copper—Calculation of Transmission Line.

PARTIAL LIST OF DIAGRAMS.

Fig. 33. The connections of a three-phase generator with composite field windings.
" 37. Shows the connections and station instruments required for the process of throwing generators in parallel, and operating them continuously, as used extensively in this country.
" 38 Temporary transformers connected to a different phase of the circuit than that in which are the permanent lamps.
" 41. Arrangement of generators at 500-KW. capacity and above, with bed-plate shaft and two bearings, designed for water-wheel connection.
" 42. Generator for direct connection to engine without bed-plate, shaft or bearings.
" 47. Connections of a two-phase motor and starting device.
" 48. The connections of a starting device arranged to give a number of different conditions of starting-voltages to suit the conditions of operation.
" 50. The connections of a starting compensator for a three-phase motor.
" 58. The connections of a three-phase motor and of a rheostatic controller for variable speeds.
" 61. The condensers and connection of a two-phase motor.
" 64. The connections of a self-starting, single-phase motor.
" 71. Single-phase arrangement of connections.
" 72. Connections for three-phase rotary converters.
" 73. Usual method of making connections for a two-phase rotary converter.
" 74. The connections of a four-pole single-phase rotary.
" 75. A three-phase arrangement of six collector rings.
" 90. The installation and connections of air-blast transformers in a long-distance power transmission.
" 96. Diagrammatical illustration of the apparatus and connections of one of the standard forms of a three-phase generator panel.
" 97. The connections in a generating station of a large power transmission plant, consisting of four 1,000-HP. generator units, one of which is held as a spare.
" 99. Diagrammatic illustration of the connections and instruments in the generating station and sub-station of a two-unit transmission plant.
" 102. The connections and method of installing an arrester for 10,000-volt circuits.
" 107. The arrangement and connections of one form of regulator for varying the pressure of an alternating current circuit.
" 115. Connections of a 2,000-volt generator.
" 116. Connections commonly used for lighting and transmission of power.
" 121. Transformer connections for changing two-phase to three-phase and back again.
" 125. Connection of both primary and secondary terminals of transformers having a ratio 10 to 1.
" 126. Three transformers Y connected in both windings.
" 127. A combination △ and Y connections.
" 128. Primary transformers are connected Y, the secondaries △.
" 129. The △ connection is sometimes made up of two transformers instead of three.
" 130. Motors connected to the secondaries of three transformers in a three-phase system.
" 132. Connections of three transformers for a low tension distribution system, by the three-phase four-wire system.
" 133-4 Connections of three-phase recording wattmeters for low and for high voltage circuits.
" 135. Method of installing and connections for a wattmeter transformer.
" 139. Connections and detail of the monocyclic generator armature.
" 144-5-6. Various methods in detail of connecting transformers to monocyclic circuits and the resultant voltages.
" 147. A third method of obtaining the proper phase relationship for motor work.
" 148. A recording wattmeter connected to measure the power delivered to motors.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser is invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 35 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to insure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—A young man who has had some experience in electric light plant, doing wiring, etc.; Southern city, steady position and good prospects; small salary to begin. Addres M. H., care ELECTRICITY.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED.—Reliable man would like to communicate with supply house or manufacturer of electrical goods with view of handling line in New York City or New England territory; experience; good references. Address HUSTLER, care ELECTRICITY.

WANTED.—Position by young man as telephone or electric light electrician; have had 6 years' experience in both; prefer Southwestern location; have been superintendent of telephone system for over one year. Address F. E. C., care ELECTRICITY.

WANTED.—Position by sober, steady married man, aged 34, anywhere in United States as superintendent or electrician of small light plant; will do line work, house wiring, lamp repairing, etc.; not afraid of work; best references; employed at present but wish to make change. Address G. E. M., care ELECTRICITY.

WANTED.—Position by a young man as general electrican; am competent inside wireman and lineman; understand care of all kinds of dynamos; 10 years' experience; capable as foreman; temperate. Address BRIGGS, care ELECTRICITY.

WANTED—Position as superintendent, chief electrician or armature winder, with a medium sized company; 12 years' experience in the above work; parties desiring a strictly first-class, sober, industrious, all-around man will do well to correspond; best of references given. Address R. B. S. care ELECTRICITY.

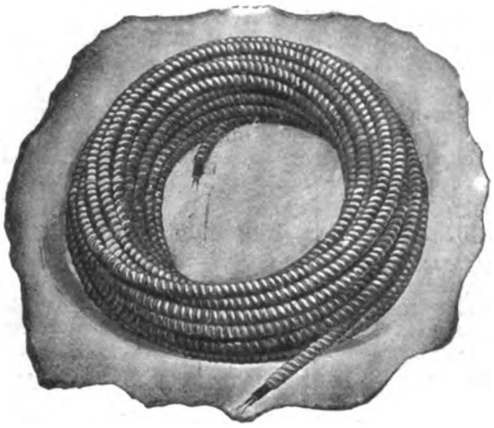
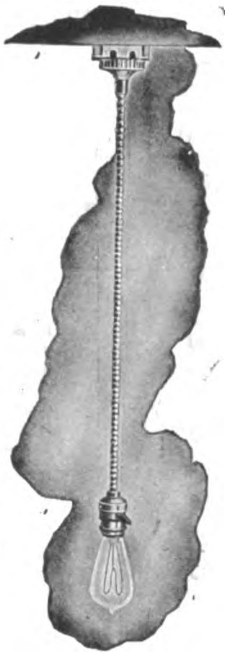
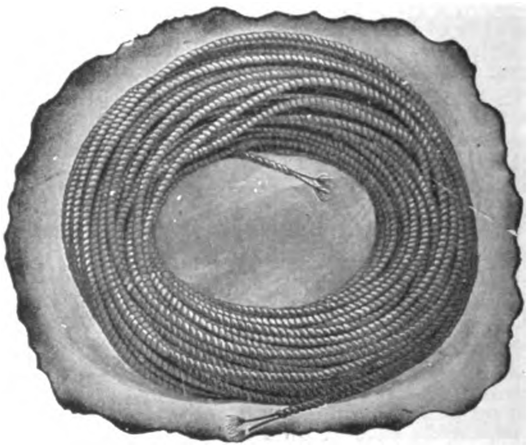
GREENFIELD

Flexible Steel Armored Conductors.







The Steel Armored Twin Conductors find special favor on account of the ease with which they can be installed, especially in finished buildings, for open construction and fished wiring on the loop system, in accordance with the requirements of Rule 24, Section "S," and Rule 48, Section "B," of the National Electrical Code.

The Steel Armored Flexible Cord for lamp pendants and portables is particularly desirable for use under all conditions requiring extraordinary service in such places as machine shops, theatres, mills, show windows, factories, etc., where flexible cords are almost indispensable and where ordinary "cord" is frequently useless.

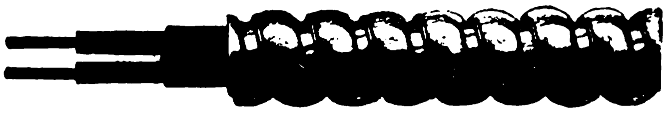
These products represent the latest and most radical advance in the art of electric wiring. Their use reduces the installation of electric conductors to an absolute simplicity.

No Elbows Required. Entire Flexibility

We will furnish cables and cords complete with armor, or we will armor conductors sent to us if insulated in accordance with the rules of the National Electrical Code.

The cordial reception accorded these new products is without doubt largely due to the high grade of insulation surrounding the conductors, the perfect mechanical protection afforded by the steel armor, and the lower first cost when compared with the metal conduits, plus conductors.

We offer to electrical contractors the greatest variety of conduits and appliances in the world. Send for Bulletin No. 02400.



Section of Flexible Steel Armored Cable.

SPRAGUE ELECTRIC CO.,

GENERAL OFFICES - - 527-531 West 34th Street, New York.

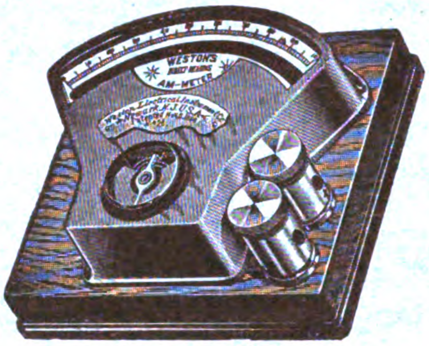
WESTON

Standard Portable Direct-Reading

VOLTMETERS, MILLIVOLTMETERS,
VOLTAMMETERS, AMMETERS,
MILLIAMMETERS, OHMMETERS,
GROUND DETECTORS and CIRCUIT TESTERS,
PORTABLE GALVANOMETERS.



Our Portable Instruments are recognized as THE STANDARD the world over. The SEMI-PORTABLE LABORATORY STANDARDS are still better. Our STATION VOLTMETERS and AMMETERS are unsurpassed in point of extreme accuracy and lowest consumption of energy.

Weston Electrical Instrument Company,

Each Issue of

ELECTRICITY.

—now contains—

AN EDUCATIONAL ARTICLE

by **R. Max Eaton**, adapted to the beginner and amateur electrician. Some of the subjects treated will be

HINTS TO THE DYNAMO TENDER,

A TALK TO WIREMEN,

POINTS ON INSTALLING AN ELECTRIC PLANT,

HOW TO TEST FOR TROUBLE,

THE TELEPHONE, etc., etc.

The articles are illustrated when necessary and will be found

INVALUABLE TO THE PRACTICAL ELECTRICIAN.

Do not fail to avail yourself of this unusual opportunity of obtaining a course in electrical engineering and a vast amount of practical knowledge Send us your subscription of $2.50 and the back numbers containing these articles will be forwarded you.
